Dec. 16th–20th (Aberdeen).—Red Cross and National Health Service Exhibition.

In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.
,, 20th–23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.
May 1st–Nov. 1st (Lyons).—International Town Life Exhibition.
July 6th–11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.
,, 8th–13th (Edinburgh).—Congress of the Royal Institute of Public Health.
Aug. 3rd–8th (London).—Sixth International Dental Congress.
,, 10th–15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.
Sept. 7th–12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.
September (Vienna).—Third International Congress for Diseases of Occupation.
(London).—Anglo-American Exhibition.
(Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.
(Auckland, N.Z.).—Australasian Medical Congress.
(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.

EDITORIAL NOTICES.

IT is most important that communications relating to the *Editorial* business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the *Editorial* staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Bradshaw Lecture
ON
GUNSHOT INJURIES OF THE ARTERIES.

Delivered before the Royal College of Surgeons of England on Dec. 5th, 1913,

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,

VICE-PRESIDENT OF THE COLLEGE; SURGEON TO ST. THOMAS'S HOSPITAL; CONSULTING SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN, SOUTHWARK.

MR. VICE-PRESIDENT AND GENTLEMEN,—Although the practice of military surgery is confined to a comparatively limited number of surgeons, yet the choice of my subject seems appropriate, since the boundary which separates civil and military surgery is indefinable, and I myself have enjoyed some experience in either field. Again, we may not forget that many Fellows of this College, only to mention such names as those of the Bells, Guthrie, and MacCormac, have devoted their attention to this subject; while our Master, John Hunter himself, founded one of his greatest works on the observations made during his period of military service.

INTRODUCTORY REMARKS.

A certain halo of romance seems to shed itself over the subject, since the history of the surgery of gunshot wounds extends to very ancient times and brings us into contact with the most famous pioneers in surgery, while no great event in the history of the world remains unspoken of in its annals. At all periods the opportunities afforded by the field of battle have exercised a strong attraction to the surgeon, both from the instinct of patriotism and the fact that in no other branch of surgery can experience be so rapidly gained. One battle can afford more material and that of more varied nature than many years of experimental work.

The progress of military surgery has some special characters of its own, thus its practice depends on opportunities which may be few and far between, while the injuries to be dealt with undergo changes and modifications dependent upon the development of the weapons with which they are inflicted.

It is of interest to remark the varying influence of civil upon military practice and of the experience gained during wars upon the civil surgeon in the history of the past. In old days there were reasons why the military surgeon should stand out pre-eminent; the field of surgery was not wide, while the operations practised in civil work were the same which the military surgeon had vastly increased opportunities of performing. Again, the actual difficulties under which military surgery has to be carried out have offered opportunities for the observation of the powers of nature, often accidental, but none the less of immense importance in the development of the great principle of conservatism in surgery. One may mention such examples as the omission of the use of boiling oil to the wound by Paré, the substitution of the ligature for the cautery in amputations, or the evidence adduced by Hunter in favour of his opinion that gunshot wounds should not be enlarged, founded on the cases of four men who escaped being subjected to this treatment in consequence of being accidentally cut off from the army and whose wounds healed readily without any complication. More recently the same influences have had an important bearing on the application of the ordinary rules of surgery to such injuries as wounds of the arteries, fractures of the bones, and perforating wounds of the abdominal cavity.

Advances in the surgery of civil life now exercise a constant influence on every branch of military practice, beyond which intervals of peace have been utilised by the military surgeon in experimental work bearing upon the effects likely to be produced by weapons introducing new ballistic problems, and varying wounding power.

A consideration of the progress which has been made in every department of military surgery is naturally too wide a field for a single lecture. It has therefore seemed to me more convenient to confine my remarks to the subject of wounds of one series of structures, the arteries. This is, perhaps, the more fitting, since the last decade has furnished us with remarkable evidence of the amenability of the wounded vessel to other forms of treatment than that of its obliteration by the application of a gross ligature.

CHANGES IN THE FORM OF THE BULLET.

Before proceeding to the actual consideration of the wounds of the vessels, it may be useful to epitomise shortly the changes which have taken place in the bullet which produces them. These changes consist in a decrease in the size and weight, and increased stability in form and structure. With these modifications in design are associated an increase in velocity and accuracy of flight and consequent greater striking force.

The most striking modification during the last decade has been the adoption by some Powers of the pointed bullet. This alteration in the outline of the bullet is designed to overcome aerial resistance to its progress and thus obtain a greater velocity of flight and striking power. While attaining these advantages the necessary shifting backwards of the centre of gravity of the bullet increases the difficulty of maintaining flight parallel to its long axis, and experimental work has suggested that this last character would result in more serious wounding capacity, since slight inaccuracies of impact suffice to result in a sudden somersault of the bullet and a consequently greatly increased surface of resistance to its entry into the body, with attendant widening of the area of tissue destruction.

Such information as is at present to hand from the recent battlefields in the Balkans does not seem to have substantiated this assumption. Surgeons indeed appear to agree that reversal does take place more frequently, especially at long distances, that the bullet is somewhat more frequently retained in a reversed or transverse position, but although this must result in a widened area of contused tissues no very marked influence on the general character of the wounds was observed. One peculiarity mentioned by Major Birrell is of practical importance—namely, the tendency of retained bullets to travel short distances in the tissues much as a needle does. Most observers regard the wounding power of the new bullet to be about equal to that of the ogival or dome-tipped bullets of corresponding calibre. They describe a similar passage of the pointed bullet in a direct course through the trunk and limbs; but a perusal of the reports leads one to believe that so-called contour wounds of the head[1] and trunk were somewhat more common than was the case with the ogival or dome-tipped bullets used in the South

[1] Mühsam: Centralblatt für Chirurgie, 1913, No. 28 Beilage, p. 104 45 thoracic, 13 contour; 22 skull, majority contour.

African war, and this occurrence is probably to be ascribed to the decrease in stability of flight the pointed bullet possesses.

INJURIES TO BLOOD-VESSELS BY MODERN AND OLDER BULLETS.

In the case of injuries to narrow structures, such as the blood-vessels and peripheral nerves, the new bullet appears by reason of its sharp point and penetrating power to effectuate even more clean and narrow perforations than its predecessors. With regard to wounds of the blood-vessels, it is of interest to note that one observer states that of 15 cases of aneurysm treated by him the bullet was retained in more than a third of the whole number.[2] I have only come across the description of one case[3] in which the retained core of a small-calibre bullet closed the lumen of the femoral artery, this occurring in the Manchurian war.

Wounds, the main importance of which depends upon the implication of the large vascular trunks, have been a common characteristic of gunshot injuries for all time, and certain features of these injuries have undergone no material change. Thus the comparatively small tendency to be accompanied by great primary hæmorrhage, the frequency with which they are followed by secondary hæmorrhage, or the development of hæmatomata or aneurysms. The most striking feature of the vascular wounds produced by bullets of small calibre is the lessened liability to afford external secondary hæmorrhage and the greatly increased frequency in which they are followed by the development of some form of aneurysm. This change no doubt depends in some measure upon improved methods of surgical treatment, but in the main is due to the limited nature of the wound, its narrow track, its comparative asepticity, and the infrequency with which extraneous matter is introduced with the bullet.

Certain special characters of the older bullet wounds of vessels, such as the temporary control of hæmorrhage by the retained bullet, the retention of the bullet within the lumen of the vessel, or the travelling of the bullet along its course, have become far less common.

Let us now consider how far the older surgeons were justified in their opinion that primary hæmorrhage due to gunshot injuries of the vessels is to be regarded as less formidable than that resulting from injuries by other weapons. I think their opinion may be fully supported by a glance at a few specimens placed upon the table.

(*3051*). *R.C.S. Museum.*—We have here a gunshot wound of the first part of the aorta; the bullet is retained within the lumen of the vessel, while the aperture of entry is partially closed by a plug of skin and adipose tissue. The man did not die until the third day.

(*34.2*). *Museum of the R.A.M.C.*—A large lateral wound of the common carotid artery and complete division of the internal jugular vein. This wound was followed by secondary hæmorrhage on the thirteenth day, and the man did not die until after a recurring secondary hæmorrhage on the twenty-fourth day.

(*34.6*). *Museum of the R.A.M.C.*—A round-shot lateral wound of the femoral artery with complete division of the vein. Secondary hæmorrhage occurred on the eleventh day and death upon the twelfth.

It will be observed that in each of the two latter specimens the wound in the artery is partially closed by firm clot, and it is reasonable to assume that under modern wound conditions the occurrence of secondary hæmorrhage would have been replaced by the formation of an aneurysm. Again, both in the case of the wounds of the carotid and the femoral the loss of substance is not more than might be dealt with by modern methods at the period at which the secondary hæmorrhage took place.

Let us now turn to the anatomical characters of the injuries inflicted upon the blood-vessels by the bullet of small calibre. It is natural to assume that the wounds will not materially differ in nature from those observed on the surface of the body. The skin and the vessel wall possess many characters in common; both are elastic and both offer but slight resistance to the passage of the bullet, the only marked difference lying in the contractility of the artery, which tends to close and at any rate temporarily diminish the size of the opening made in its wall.

We are aware that in elastic structures like the blood-vessels the area of tissue destruction will be less extensive than one corresponding to the calibre of the bullet; also that the revolution of the bullet and the force it exerts laterally as a result of its generally conical form tend to displace the component parts of an elastic cord, such as a nerve, without free transverse division of the fibres.

The injury to a blood-vessel may be either of the nature of a contusion or a wound, while the extent of the lesion varies according to the accuracy with which the course of the vessel is traversed. With rectangular impact a notch, a clean perforation, or complete division results; when the impact is oblique, more extensive loss of substance follows, such injuries reaching their most marked degree when the bullet courses for some distance directly along the vascular cleft. It need only be mentioned that when the wound is complicated by a fracture of a bone the injury to the artery may be produced by a spicule of bone and partake of the nature of a puncture or a more or less complete laceration.

CONTUSION OF THE VESSEL WALL.

It is difficult to gauge the importance of this injury. There is no doubt that the contusion may be sufficiently severe so to damage the tissue of the vessel wall that in the event of infection and suppuration the injured area may give way, and separating give rise to secondary hæmorrhage. That this accident may occur is a common experience. Judging by my own observation, I think it is also probable that contusion may be followed by the development of a cicatrix, which permanently narrows the calibre of the vessel, and may possibly lead to its complete obliteration.

A specimen of Mr. Guthrie's preserved in the Museum of the Royal Army Medical College shows the femoral vessels entirely occluded in the neighbourhood of a suppurating bullet track passing behind them. In this instance, of course, the greater contusing power of the old leaden bullet must be borne in mind. In the case of aseptic wounds I doubt if contusions often give rise to troublesome after-results.

COMPARATIVE FREQUENCY AND RESULTS OF VARIOUS FORMS OF WOUNDS.

Some information is to hand as to the comparative frequency and results of the different varieties of wound of the vessel wall. Thus Surgeon-General W. F. Stevenson, A.M.S., in his report[4] on the South African campaign, includes the nature of the lesion

[2] Frisch: Ibid., p. 710.
[3] Kikuzi: Beiträge zur Klinischen Chirurgie, Band l., p. 21.
[4] Report on the Surgical Cases treated in the South African War, 1899-1902. London, 1905.

in 16 cases of aneurysm which underwent operation. Of these 8 were lateral wounds, resulting in 6 arterial and 2 arterio-venous aneurysms. Four were perforations, resulting in 1 arterial and 3 arterio-venous aneurysms. Four were complete divisions. Saigo[5] includes the nature of the lesion in 34 cases. Of these, 21 were lateral wounds resulting in 13 arterial and 8 arterio-venous aneurysms; 11 were perforations resulting in 4 arterial and 7 arterio-venous aneurysms; and 2 were complete divisions. In a total of 50 cases we find 29 lateral wounds = 58 per cent.; 15 perforations = 30 per cent.; and 6 complete divisions = 12 per cent. Also that perforation of the vessels more frequently leads to the development of an arterio-venous aneurysm (60 per cent.) than does a lateral injury (40 per cent.).

Naturally little information exists as to the results of incomplete lesions, but two observations of great interest may be noted. In one a graze of the femoral artery resulted in the development of a protuberance the size of a hazel nut accompanied by the signs of a traumatic aneurysm. An attempt was made to cure the condition by suturing the outer coats of the vessel over the weakened spot (Babasinoff). This procedure failed, the aneurysm again developing, after which the artery was successfully ligatured. The case is one of much interest also as demonstrating the necessity of the apposition of the intima for a successful arterial suture. In the second case (Stevenson)[6] (Case 28) a non-penetrating injury of the axillary artery was followed on the twelfth day by the formation of an arterial hæmatoma. On the fourteenth day this was laid open and a graze one inch in length implicating the outer coats of the vessel was discovered which had given way in the centre

With regard to the comparative frequency of lateral wound, perforation, or complete division, it is probable that the numbers given above are not strictly accurate, since they are founded on observations made on lesions followed by the development of aneurysms, and fail to take into account the large number of cases in which hæmorrhage either ceased spontaneously or led to death. One or two points of interest, however, arise from the consideration of Table I. together with Table II. First of all, the frequency with which any artery is hit naturally corresponds directly with its calibre and the length of its course. Secondly, if we analyse 42 cases we find that the frequency of perforation depends not only on the width of the vessel, but also on its comparative fixity of position; thus, perforation of the femoral and popliteal vessels is common, while the axillary artery, a trunk but little smaller, frequently escapes with a lateral injury.

TABLE I.—*Cases of Lateral Wound and Perforation.*

(From the Statistics of Saigo and Stevenson.)

—	Lateral wound.	Perforation.	Total.
Carotid	1	1	2
Subclavian	2	1	3
Axillary	6	1	7
Brachial	10	1	11
Femoral	7	8	15
Popliteal	1	3	4
Totals	27	15	42

[5] Deutsche Zeitschrift für Chirurgie, Band lxxxv., 1906, p. 577.
[6] Loc. cit.

The question of the frequency of complete severance of a large artery is more difficult to determine, since it is probable that a considerable proportion of the instances in which it occurs are followed by early death from hæmorrhage, but it is significant that in the series from which the above small table is taken complete division of the artery was observed six times, and that in five of these instances the popliteal was the vessel implicated; in the sixth the femoral artery was completely divided by a bony fragment from the femur. The liability of the popliteal artery to complete division is probably explicable on two grounds: (1) That the artery is commonly struck in the condition of full tension corresponding with the extended position of the limb; and (2) that except when the bullet enters from the posterior wall of the space it has to perforate resistant structures, and hence may be altered in form and wounding properties.

ANATOMICAL CHARACTERS OF THE WOUNDS.

As to the anatomical characters of the wounds we are indebted to Brentano[7] for the only accurate description I have met with. With regard to lateral wounds, he points out that the margins are tattered irregularly, giving the impression of having been gnawed out; again, that a lateral wound involving more than half the circumference of the artery gapes widely longitudinally, acquiring a greatly increased size, in consequence of the elastic nature of the vessel wall. The artery hence becomes incapable of conducting the blood and the injury is comparable to a complete division.

Perforating wounds do not separate so widely in consequence of the continuity of their margins; the loss of substance is also less, the size of the opening not equalling the calibre of the bullet. Perforations cause some obstruction to the circulation due to the escape of blood, and the effect upon the vessel is to produce some proximal and a lesser distal dilatation of the lumen.

In proceeding to a consideration of the results of these injuries, it is of interest to premise that we are here met with one of the most striking anomalies of military practice, since we are about to deal with a series of complications not one of which would be met with did not the exigencies of the work in the field render it impracticable to abide by a fundamental rule of surgery—i.e., that a bleeding vessel should be secured at the first possible moment after its injury.

PRIMARY HÆMORRHAGE.

The question as to the proportion of vascular injuries which lead to early death upon the field of battle seems one almost incapable of an answer. There can be no doubt that it is a large one, and in support of this it is only necessary to mention the fact that hæmorrhage from, or aneurysms developing in connexion with, the large arteries of the trunk practically receive no mention in the large series of cases reported from recent campaigns. Operations upon the great vessels of the neck and the limbs are frequent, but except for an occasional ligature of the external, and still more rarely of the common iliac, vessels we find no mention of the vessels of the trunk. It seems therefore reasonable to assume that wounds of these vessels lead with few exceptions to rapid death. The same result probably follows a certain proportion of the wounds of the large vessels in the limbs also.

In connexion with this subject we may conveniently consider the question of spontaneous

[7] Brentano: Archiv für Klinische Chirurgie, vol. lxxx., 1906, p. 395.

healing of the larger vessels. I think there is every reason to conclude that this may be either immediate or remote and takes place with a certain degree of frequency on the following grounds. In the first place, clinical observation of wounds traversing the course of large vessels, as the subclavian or the femoral, has demonstrated the presence of local murmurs pointing to local constriction of the vessel, also diminished pulsation in the peripheral circulation. Again, such diminished pulsation may be temporary. It may, of course, be suggested that in these instances the vessels have suffered contusion only, and that the signs are dependent on temporary thrombosis of the vessel or on pressure exercised by cicatricial tissue in the wound track on the artery. Hence the importance of definite evidence derived from observation of the conditions found in certain varieties of aneurysm.

Spontaneous Cure as an Immediate Process.

First, as to the primary occlusion of the vessel by a provisional thrombus. This has been observed in several cases where the injury has been followed by gangrene of the limb (Manteuffel, Subbotich, and others). The gangrene in such cases is comparable to that which sometimes follows primary proximal occlusion of the vessel by ligature.

Then as to immediate cicatrisation of the wound. In Surgeon-General Stevenson's report (Case 96, under the care of Dr. Archibald Young) the following conditions were found in a patient who died of enteric fever 15 days after receiving a wound which perforated the superficial femoral artery and vein antero-posteriorly at the apex of Scarpa's triangle. The wound of entry into the artery was closed by a small firm clot embedded in the posterior aspect of the sartorius; the small circular exit wound was attached to a similar opening in the opposed surface of the vein, while the wound of exit in the vein was "nearly cicatrised." No extravasated blood was present either around or between the vessels.

A more astonishing observation was made by Brentano in the case of a wound traversing the abdominal aorta just above the origin of the renal arteries, and then passing through the liver. The patient died upon the seventieth day from a subphrenic abscess in connexion with the wound of the liver. The following condition was found in the aorta. The entry wound visible on the outer aspect of the vessel was circular and looked like the proximal extremity of a small branch which had been cut off. The exit wound was slit-like in character. When the vessel was first opened the wounds were scarcely visible on its inner aspect. Both were firmly closed, while the exterior of the vessel was coated with a layer of plastic lymph, quite separate from the suppurating blood clot which lay around. This case recalls to my mind that of a patient I saw die suddenly with signs of an abdominal hæmorrhage two days after the receipt of a perforating wound in South Africa.[8]

As to the condition discovered during operations, in 5 out of 11 perforations in Saigo's series of extirpations of aneurysm, one of the two arterial wounds had cicatrised at the end of 6 months, 4½ months, 39, 37, and 25 days respectively. In one of these cases the scar bulged, and in the second a small consolidated aneurysmal sac was present at the site of the wound.

A second method of occlusion is by the adhesion of the surrounding vessels and nerves; such cases were observed by Sir W. MacCormac and Sir William Stokes. A striking instance observed by Major Holt is recorded in Spencer's "Gunshot Wounds" (p. 68).—"In dissecting out the upper end of the divided ulnar nerve in the upper arm I came across the divided brachial artery tied up in scar-like tissue. Astonishment and curiosity led me to free the proximal end, and it at once bled as a normal brachial artery would. I tied it, and to confirm matters eventually found the lower end also in the scar." Brentano, who draws special attention to this mode of healing, mentions a similar observation. It is noteworthy that in all four instances the brachial was the artery concerned.

Remote Process of Healing.

Secondly, spontaneous cure may be the terminal result in arterial hæmatomata which contract to form circumscribed traumatic aneurysms and eventually consolidate. Of this sequence of events I have seen several instances, and they have been observed by many surgeons. I think we may conclude that the opening in the artery gradually contracts, the flow of blood into the aneurysm is lessened, and consolidation of the sac follows as a result of the deposition of laminated clot.

A case of great interest is related by Saigo in which the femoral artery was completely severed by a spicule of bone. The injury was followed by the development of two small aneurysmal sacs, one on either side of the proximal end of the vessel, while the distal end was completely occluded.

Aneurysmal Varix.

Thirdly, I think the development of a pure aneurysmal varix can only be regarded as an instance of the permanent arrest of hæmorrhage by a spontaneous process of healing. In many such cases the primary absence of any trace of extravasated blood in the sheath of the vessels, except such an amount as may have ensured the firm lateral adhesions of the two vessels, points to a process resembling that following the ligature of a vessel. The opening is at first occluded by clot, formed on the margins of the wound in the vessels, which temporarily arrests the passage of the blood into the vein; this clot persists until in the process of healing the intima of the artery has become continuous with that of the vein. The provisional clot is then absorbed or washed away, as is the temporary thrombus developed after ligature, and we get the development of the characteristic thrill and murmur with the establishment of the arterio-venous communication. The period occupied by this process corresponds with the interval of days or weeks commonly noticed between the reception of the wound and the development of the purring thrill and murmur. Lastly, an aneurysmal varix may heal spontaneously many months after its development. In my book on the wounds of the South African war two instances of spontaneous cure of this nature in carotid arterio-venous aneurysms are described; the thrill and all symptoms disappearing some months after the application of a proximal ligature to the artery. A case of spontaneous cure where the communication was supposed to be between the innominate vessels is also related there, and many other instances of this sequence of events have been observed. An instance of a still more remote closure of the opening in an aneurysmal varix is recorded by Sir W. Osler.[9] The patient was seen by me in 1900 with the classical

[8] Surgical Experiences in South Africa, p. 117.

[9] THE LANCET, Nov. 1st, 1913, p. 1248.

signs of an aneurysmal varix of the axillary artery of 22 years' standing. When he died in 1909 no trace of any communicating opening could be discovered between the vessels, although both were dilated and the walls were much thickened. The drawing in THE LANCET shows the vessels in intimate relation at the point of greatest dilatation.

These cases appear to afford definite evidence of the cure of a wounded artery either by an immediate or a remote process.

THE DEVELOPMENT OF ANEURYSMS.

The frequency with which wounds of arteries are followed by the formation of the different kinds of aneurysm is not possible to determine accurately, since so large a proportion of vascular wounds in war escape record. Table II., however, shows the general distribution of the lesions in 283 cases collected from reports of the South African (98), Manchurian (121), and recent Balkan (64) campaigns. Table III. gives, in addition, a rough estimate of the proportion in which the various forms of aneurysm occurred in 162 instances:—

SECONDARY HÆMORRHAGE.

The decrease in frequency of external secondary hæmorrhage in gunshot wounds only brings them into line with the injuries of civil life, the decrease bearing a direct proportion to the decrease of infection and suppuration. When the small number of cases needing treatment by amputation or ligature mentioned in the reports of recent wars is contrasted with the formidable list recorded in the report of the older campaigns the change is striking indeed. It cannot, however, be too strongly urged that, although infection is less common, yet the second cause of secondary hæmorrhage—disturbance of the wound incident on the transport of the patient—exists in an equal or exaggerated degree, and is unaffected either by the anatomical nature of the wound or the method of treatment adopted.

External hæmorrhage is replaced by bleeding into the tissues, the extension of localising arterial hæmatoma, or increase of blood collections in the pleuræ, peritoneal cavity or the joints. These accidents are sufficiently common to render absolute the rule that no subject of a wounded vessel should be submitted to the dangers of transport except in the case of actual necessity, and then only with the wounded part as far as possible immobilised.

TABLE III.—*Forms of Aneurysm.*

—	Stevenson, South Africa.	Saigo, Manchuria.	Subbotich, Balkans.	Total.	Per cent.
Arterial, diffuse or localised	31	21	43	95	58·6
Arterio-venous aneurysm	33	10	16	67	41·3
Aneurysmal varix	—	5	3		
Totals	64	36	62		

It must be borne in mind, however, that these tables merely record the survival of the fittest, since they are based on cases treated in the base hospitals, and that a considerable number of small traumatic aneurysms and a still larger number of pure varices escape not only the surgeon but also any record whatever.

THE TREATMENT OF WOUNDED ARTERIES.

The question, At what moment should the

treatment of a wounded artery be undertaken? in military practice is one fraught with the greatest difficulty. Reasons have already been given for believing death from primary hæmorrhage when the great arteries of the trunk are implicated to be the common result, and to that point no further reference need be made; but in the case of wounds of vessels in the neck and limbs we know that a number might be saved who die from secondary hæmorrhage or gangrene, and that a large number develop aneurysms which need operations of some severity before they are cured.

It is clear that primary ligature of the vessel would ensure the life and avoid the dangers attendant upon the aneurysm to this latter class did not the exigencies of military practice forbid the adoption of the common rule of surgery in the great majority of instances. If the patient is bleeding seriously, manifestly the ordinary rule must be followed, but if hæmorrhage is slight or has ceased spontaneously, pressure and a first dressing will be applied and the patient sent to the rear. He now passes through the hands of the medical officers of the bearer company, the field hospital, the stationary hospital, and possibly of the ambulance train, before he reaches the haven of the base hospital, at which alone extensive operations can be performed under the best conditions.

Once entered upon, until this transitory period is ended, not only are the general conditions and surroundings unsatisfactory as far as the operating surgeon is concerned, but experience has also abundantly proved the local condition of the wound to be eminently unsuitable for direct treatment. The wound cavity contains a large amount of clot and its walls are stiffened by extravasated blood and reactionary effusion. These conditions render the employment of drainage a necessity, a provision rendering the wound readily liable to the dangers of infection during transport.

These difficulties existing with regard to the comparatively simple operation of ligature acquire still more significance in considering the far more delicate operation of suture, which requires not only greater skill, but also more satisfactory surroundings, even putting on one side the question as to whether the recent gunshot injury of the artery is in itself a class of wound suitable to primary suture as to its fitness for direct union, or as to the risks of consequent gross thrombosis of the vessel. Little actual experience of primary suture has been gained, but such as exists is not of a nature to encourage the hope of any great future for this method of treating wounded arteries in military surgery.

I think it is indubitable that in the present state of surgery direct ligation when necessary is likely to remain the only operation suitable for application to the primary injury, and this rule is still more applicable to the treatment of external recurrent or secondary hæmorrhage.

In military surgery it is, then, chiefly in the treatment of the secondary consequences of wounds of the arteries that the question of the relative applicability of ligature or suture of the vessel comes into consideration, in spite of the fact that a few isolated primary operations for suture have been undertaken with somewhat doubtful results.

Treatment of Arterial Hæmatomata and Aneurysms.

This brings us to the question of dealing with arterial hæmatomata, traumatic aneurysms, arterio-venous aneurysms, and aneurysmal varices. Both the recognition of aneurysm as a condition amenable to operative treatment alone, and every method of treatment now in use, can be traced to the most ancient times. Arterio-venous aneurysm was described by Rufus of Ephesus in the first century, while Galen in the second century speaks of it as a well-known condition. Common during the long period that bleeding from the bend of the elbow was a routine practice, its frequency diminished as its source of origin became limited to occasional stab wounds and injuries from shot guns, again to become again enormously increased in connexion with the employment of the bullet of small calibre.

The simple employment of the ligature was supplemented between the first and fourth centuries by the addition of incision combined with proximal and distal ligature of the artery by Antyllus, while Philagrius introduced the further procedure of extirpation of the aneurysmal sac. After an interval of more than 1200 years the method of Philagrius was re-introduced by M. G. Purman in 1669, who successfully treated three cases of brachial arterio-venous aneurysm by proximal and distal ligature of the artery, combined with extirpation of the sac.[16] From that period methods of treatment have varied, but no really new procedure has been employed until the application of the method of suture to wounded blood-vessels opened up a new avenue.

The history of the application of a method of suture to an artery commenced with the closure of a wound of the brachial artery by "twisted suture" on a pin by Hallowell in 1759, while lateral suture of a vein was first performed by Schede in 1882. The first lateral suture of the femoral artery was made by Postempski in 1886, and the first successful complete circular suture on the human subject was performed by J. B. Murphy in 1896 of the femoral artery by his invagination method, this operation being followed by a similar one upon the axillary artery. Since that period the technique of suture has been widely developed both in experimental work and in surgical practice, while the late war in the Balkans has allowed a fairly extensive trial of its suitability to the treatment of gunshot wounds.

The main outcome of the experience in the treatment of vascular injuries gained in the South African war was to emphasise the dangers of Hunterian ligature at the seat of election, especially in the vessels of the lower extremity, and to suggest various methods of dealing with arterio-venous aneurysms and varices. Of these latter, ligature of the artery above and below the communication, leaving the vein untouched, received the impress of official recognition, while double ligature of both vessels, proximal ligature of the artery with ligature of the vein above and below the opening (Lewtas), were performed successfully, and a number of cases of simple proximal ligature (Anel), especially in the neck and upper extremity, gave good results.

In the Manchurian campaign the chief change consisted in the greater frequency with which ligature of the vessels was accompanied by excision of the portion of the vessels involved together with the sac itself, and in Syme's modification of the method of Antyllus, in which the sac is opened prior to the application of the ligatures to the wounded vessel, called by Kikuzi "intrasaccular direct ligation." A series of results published by Saigo will suffice to illustrate

[16] A. Kohler: Archiv für Klinische Chirurgie, vol. l., p. 333, 1906.

the success with which extirpation was attended in skilled hands. (Table IV.) In Saigo's practice operation on the aneurysm was preceded by some days or weeks' digital compression, with a view to encouraging the development of the collateral circulation.

TABLE IV.—*Saigo's Series of Cases.*

Extirpation	11	11	—	—
Ligature of artery above and below. Vein untouched ...	2	1	1	Femoral. Gangrene, amputation.
Antyllus	2	1	1	Hæmorrhage. Secondary ligation.

In the recent war in the Balkans the method of suture of the vessels has been somewhat widely employed in the treatment of the secondary consequences of wounded arteries. The results of this method of treatment in the Belgrade State Hospital have been collated by Dr. V. Subbotich, and were communicated to the Section of Naval and Military Surgery at the recent seventeenth meeting of the International Congress of Medicine. I am much indebted to Dr. Subbotich for a supplementary report regarding such of the cases as to which the result was unknown at the time his paper was written.

Direct and Proximal Ligature.

We may now proceed to compare the various methods of treatment employed during the last decade. First as to the time-honoured measure of ligature in its various applications. I think the entire concourse of surgical opinion is opposed to the operation of ligation at the seat of election. The tragic history of its employment in the treatment of secondary hæmorrhage in the older campaign has been followed in the more recent ones by an only qualified improvement in its application to the treatment of traumatic aneurysms.

TABLE V.—*Cases of Ligature in South African War.*

—	No.	C.	D.	Percentage-
Secondary hæmorrhage, direct ligation	8	6	2	25
Secondary hæmorrhage, proximal ligation	11	7	4	36·3
Arterial hæmatoma, direct ligation	27	27	—	
Arterial hæmatoma, proximal ligation	16	16	—	
Circumscribed traumatic aneurysm, direct ligation	4	4	—	
Circumscribed traumatic aneurysm, proximal ligation ...	14	13	1	
Arterio-venous aneurysm, proximal ligation	14	6	3	21·4

57·1 per cent. gangrene. 25 per cent. of these died after amputation. R., 11; amputations, 6.

In the small number of cases noted in the South African war (Table V.) we find that 36·3 per cent. of the cases of secondary hæmorrhage treated by proximal ligature died. The result in 30 cases of arterial aneurysm was better, no instances of gangrene being reported and only one death, 3·3 per cent., but in a number of these the proximal ligature was of the nature of an Anel's operation. The worst results were those following proximal ligature for arterio-venous aneurysms. Here of 17 patients 3 died, and in 8 the operation was followed by gangrene. If three operations on the carotids are subtracted we find 14 cases of ligature of arteries of the extremities with 2 cases of gangrene in the upper and 6 in the lower limb—thus a percentage of 57·1 of gangrene and 21·4 of death.

A distinction must, however, be certainly drawn between the operation of Hunter and that of Anel. I myself saw three cases of proximal ligature of the carotid followed by immediate cure of the aneurysm and remote spontaneous cure of the arterio-venous communication of two, while the same result was observed in some cases of brachial arterio-venous aneurysms where a proximal ligature was placed close above the sac. These results of proximal ligature have been fully confirmed in the Manchurian campaign. The operation of simple direct ligature may, on the other hand, be regarded as highly successful; of 31 cases of arterial aneurysm so treated and recorded in Stevenson's report all were cured.

Modified Operation of Antyllus.—Extirpation.

In the Manchurian campaign Kikuzi, Alexandrow, Koratkoff, and others employed Syme's modification of the operation of Antyllus with much success. Kikuzi,[11] who calls the method "intrasaccular direct ligature," claims the following advantages for it: 1. Ease of application. 2. The short time required for its performance. 3. The practicability of performing the operation under local anæsthesia. 4. The limited extent of the vessels excluded. 5. Few collateral branches are injured, and thus circulatory disturbance and danger of gangrene are diminished. Kikuzi employs an Esmarch's bandage in operating on the extremities or follows Syme's method of introducing a finger into a small opening made in the sac, where the elastic tourniquet is inapplicable. He records two successful cases, one of the carotid and one of the external iliac arteries, where Syme's method was employed.

In the Manchurian campaign extirpation of the aneurysm together with the portion of the vessels from which it sprang after ligature above and below the aneurysm was also employed. Saigo[12] reports the results of 26 aneurysms treated by this method, with one death (immediately following the operation), 3·8 per cent. Of the 26 aneurysms 15 were arterial and 11 arterio-venous. The series was practically unaccompanied by serious gangrene, since only gangrene of the thumb in a case of axillary aneurysm, and of the toes in a femoral aneurysm, 7·6 per cent., occurred. (Table V.) A series of 5 cases of arterial and 9 of arterio-venous aneurysm thus treated are also recorded by L. Bornhaupt, in which no single accident occurred.[13]

The procedure of extirpation, however, is a serious one, needing considerable time for its performance, and in spite of this excellent series of results, I think the cases suitable for its employment need careful discrimination.

THE METHOD OF SUTURE.

Let us now proceed to consider more fully the latest addition to methods of treatment. Suture, whether lateral or circular, may well be considered the ideal procedure, since by it alone can the normal circulation be re-established and maintained, and sufficient evidence has now accumulated to allow a provisional judgment being given as to its advantages.

1. The method of suture obviates the necessity of any dependence on the establishment of a collateral route for the circulation. This even in the healthy young men, commonly the subjects of military surgery, must be regarded as an important feature, the more so that in the early stages of arterial hæmatomata blood extravasation may interfere with the compensatory enlargement of quite normal collateral systems.

2. By the method of suture no loss of length of the artery is suffered, and the least chance of destroying any collateral branches is attained, the latter point being of some weight should the suture be followed by local thrombosis.

3. By this method not only is the immediate vitality of the limb less endangered, but the chances of permanent deficient nutrition consequent on an imperfect and insuffieient blood supply are lessened or abolished.

The Immediate Vitality of the Limb.

There seems no question that the first two of these propositions must be conceded; the third needs further examination. First, as to the immediate vitality of the limb. It is stated that a review of published cases shows that gangrene follows the operations of ligature in from 6 to 12 per cent. of all cases. This is probably not an excessive estimate if both traumatic and spontaneous aneurysms are taken into account, but I think if the traumatic aneurysms are considered separately, and further, if the purely arterial aneurysms are considered apart from those in which an arterio-venous communication is present, that the ligature of a healthy artery is not to be regarded as so dangerous a proceeding.

In the case of 31 direct ligations of large arteries for arterial hæmatoma and circumscribed aneurysm in the South African war gangrene did not occur in a single instance; and in 30 cases of proximal ligature for the same condition only one case of gangrene (following ligature of the femoral) occurred, 1·6 per cent., and one patient died, 1·6 per cent., from septicæmia one month after the operation, the aneurysm itself being cured. The bad results followed the operation of proximal ligature for arterio-venous aneurysms, an operation which except in some special instances should never be performed.

Again, if the 26 extirpations combined with ligature by Saigo are considered, gangrene occurred in only two instances, and here was minimal in degree, resulting in the loss of a thumb after ligature of the axillary artery, and of the toes in one case of ligature of the femoral artery.

To compare with these results we may take, first, 31 cases of suture performed in civil practice, collected by Tscherniachowski,[14] including 15 isolated sutures of the artery, 7 isolated sutures of the vein, and 9 sutures of artery and vein. Of the aneurysms treated 11 were arterial, 20 arterio-venous. Amongst these cases gangrene also occurred twice, once in a remarkable instance in which repeated secondary hæmorrhages followed suture, resuture, ligature, and amputation; and in the second as the result of an infection causing gaseous cellulitis. In the matter of gangrene these statistics show a slight advantage.

In 22 cases of arterial suture collated by Subbotich during the Balkan war gangrene occurred once after lateral suture of the popliteal artery and vein, and once after circular suture of the external iliac artery combined with ligature of the vein. In a case of incipient gangrene following a wound of the popliteal artery lateral suture failed to arrest the process. If the two cases only are counted there is a percentage occurrence of 9 per cent.

It is obvious that these numbers are far too small for any definite deduction to be drawn; again, that they probably represent only a small proportion of the cases operated upon; but they, at any rate, go to prove that under existing conditions the employment of suture has not abolished the occurrence of gangrene.

The Later Nutrition of the Limb.

As to the question of permanent lowering of the nutrition of the limb, in civil practice, given fair condition of the blood-vessels, this sequela has not been one which in the past has attracted serious attention on the part of the surgeon. In fact, I think surgeons have looked upon the ligature of a large artery as a satisfactory operation in regard to its permanent results. In military practice in my own experience I have seen bad results; thus a condition not appreciably differing from that of Volkmann's contracture of the leg in two instances after ligature of the popliteal artery for arterial hæmatoma, and again gangrene of the leg following a slight injury some months subsequently to ligature of the superficial femoral artery. In these cases, however, I think some weight must be given to the widespread nature of the blood extravasation and dissection of the limb, the unsatisfactory conditions under which the cases were treated (both the popliteal cases came from field hospitals), and perhaps to the neurasthenic state of the patient himself.

Frisch,[15] on the examination of 10 cases in which arteries had been tied at periods of from one to eight years, found only 4 sound limbs; in the remaining 6 trophic changes were present. Again, Koratkoff estimated the peripheral blood pressure in 17 patients in whom arteries had been tied, and found it to be: in 7 cases, less than half that of sound limb; in 4 cases, about half; in 4, more than half; and in 2, equal to that of sound limb; and in one of the last two cases the estimation was made only six weeks after the operation. These numbers speak for themselves, but, of course, it still remains to be seen whether a series of sutures will show better results.

Thrombosis.

Intimately connected with the occurrence of gangrene is the question of how frequently thrombosis follows the operation of suture. We know from the results of experimental work that thrombosis does occur in a certain number of instances; further, that its occurrence is determined by even small errors in an exacting technique.

Again, the clinical observation[16] of a firm thrombus 1½ cm. in length on the sixth day,

[14] Deutsche Zeitschrift für Chirurgie, Band cxxiii., 1913, p. 1.

[15] Archiv für Klinische Chirurgie, Band lxxix., p. 515.

[16] Von Manteuffel: Ibid., Band lxxxi., p. 1.

extending from the site of a lateral wound in the femoral artery and giving rise to gangrene of the leg, is suggestive of the risk of a wound inaccurately closed. A case of spontaneous thrombosis of the femoral artery after complete division, accompanied by no local blood extravasation, is also recorded by Subbotich. In this incipient gangrene was noted.

A precise determination as to the sequence of thrombosis to suture of the artery in surgical practice is hardly possible, since, even does the artery thrombose, the patient is in no worse plight than if a ligature has been applied. The only useful indication is to be sought in the peripheral blood pressure, but of this in most cases we have only the rough estimate which can be obtained by feeling the pulsation in a distal artery. In Tscherniachowski's table of 16 lateral sutures, among 14 cases which survived the peripheral pulsation is noted as weaker in two cases, while in 2 weak pulsation noted before the operation became normal after the artery had been sutured. Among 9 cases of circular suture of the artery, in 2 instances no return of pulsation in the posterior tibial or dorsalis pedis followed suture of the popliteal artery, while in 1 the renewed pulsation was observed to become weaker. In 1 case of suture of the axillary and 1 of the femoral artery pulsation returned when none had existed prior to the operation. In 4 further cases, where both artery and vein were joined by circular suture, in 1 case (Lexer) the peripheral pulse was noted to be weaker at the end of eight months, possibly as the result of cicatricial contraction at the site of union. In 2 out of 24 cases in Subbotich's paper the development of gangrene points to the occurrence of thrombosis of the artery.

Other Accidents.

Lastly, we have to consider how far the practice of suture is exempt from the other accidents which sometimes follow upon operations on the arteries. Unfortunately. not very much information is to hand on this subject. The mere failure to be able to apply the method either from the discovery of a defect too extensive to allow of repair, or from technical difficulties dependent upon the position of the wound, is of little moment, since the exploratory operation may equally well be employed for ligation of the vessel.

The more serious question of failure in competency of the suture itself, either from primary insufficiency of the stitch or from secondary infection, is more important. Among the cases collated by Tscherniachowski no such accidents are recorded, but even here the fallacy depending on the fact that unsuccessful operations are not freely published must be given due weight. Z. von Manteuffel records a case in which a lateral suture applied to the femoral artery on the sixth day leaked, and had to be supplemented by a double ligature, and here one may emphasise the fact that von Manteuffel himself has questioned the suitability of recent wounds to primary suture by reason of their contused nature. Again, Subbotich, while he records the fact that secondary hæmorrhage followed none of the 22 operations performed in the Belgrade Hospital, adds in speaking of arterial hæmatoma: "The hæmatoma must be removed, the bleeding vessels dealt with, and the cavity drained after complete closure by suture of the incision wound by other openings specially made for the purpose. In these cases secondary hæmorrhage may occur after several days and be very serious."

COMPARATIVE RESULTS AND CONCLUSIONS.

The comparative results obtained in 41 cases of ligature and 24 cases of suture in the Belgrade State Hospital is as follows: Ligature, 41 cases; gangrene, 6 cases (14·6 per cent.); and deaths, 4 cases (9·75 per cent.). One death due to softening of the brain and pneumonia after ligature of the carotid, 1 from secondary hæmorrhage, 1 from sepsis, and 1 from anæmia and exhaustion. Suture, 24 cases; gangrene, 3 cases (12·5 per cent.); and deaths, 2 cases (8·3 per cent.). These figures, while exhibiting no very striking superiority for the new method in immediate results, at least thoroughly justify its employment, and this justification may be strengthened in the future if it can be shown that the permanent result is better in regard to the condition of the limb. On this latter point I can only quote again Subbotich: "On seeing some months later cases that have been operated upon, we find *both* in cases of ligation and of suture, greater or less interference with the functions, such as muscular weakness, neurasthenia, œdema, &c. On the other hand, we find some quite ideal cases."

What conclusions are we to draw from these results? Operations for wounds of the arteries may have to be undertaken during three distinct periods, which may be classed as primary, intermediate, and secondary.

Primary Operations.

1. The operation of choice for primary hæmorrhage from a gunshot wound in the field is direct ligature. In support of this opinion may be advanced the comparative simplicity of the operation and its applicability even under adverse conditions. Primary ligation should be confined to cases in which hæmorrhage is obviously endangering life.

The objections to the method of suture are twofold; first, the local conditions are not favourable in consequence of the contused and tattered margins of the opening in the artery commonly met with. The anatomical character of the wound, in fact, is unfavourable both to the safe closure of the wound and to the avoidance of subsequent thrombosis in consequence of the impracticability of ensuring an accurate apposition of the intima. One has only to consider the fact that the comparatively slight damage attendant upon the use of toothed forceps to facilitate the introduction of the suture is generally considered enough to risk subsequent obliteration of the vessel by thrombosis to come to the conclusion that the ragged contused margins of a gunshot wound are ill-suited to suture. Secondly, although these difficulties are to be avoided in certain cases by excision of the damaged portion of the vessel and circular suture of the proximal and distal ends, yet this undertaking needs so much time, skill, and perfection in the general surroundings that it cannot be regarded as a practical procedure.

In this stage there is no doubt that a line must be drawn between the wounds of civil practice, in which suture may be advisable, and the wounds produced by bullets of small calibre. When primary operations are necessary and the wounded artery is dealt with during the first three days the difficulty of evacuating the clot may not be great, while the procedure saves much time and the general nutrition of the limb suffers less than if a secondary operation is waited for. Further, where incipient gangrene threatens, the limb may be rescued by relieving the collateral circulation from the pressure exerted by the hæmatoma. The latter

fact is especially to be borne in mind in the case of popliteal hæmatomata. (Z. von Manteuffel.)

Intermediate Operations.

2. As to intermediate operations, it has already been pointed out that the wounds are ill-suited to any form of treatment except the simplest. The evacuation of clot is difficult, the stiff œdema of the arterial wall itself, as well as that of the boundaries of the cavity (Brentano), and the probability of the necessity of providing drainage negative the chances of a successful suture, and render the prognosis even of a simple direct suture doubtful.

The experience of all recent campaigns has been to show that in the absence of secondary hæmorrhage or rapid extension of the hæmatoma the general tendency is towards contraction and localisation of the extravasated blood and to diminution in the size of the arterial wound, while the conditions improve for the successful application of treatment.

The unsuitable character of these injuries at this stage for the employment of proximal ligation at the seat of election has already been dwelt upon. It is unsafe, not only from the risk of further secondary hæmorrhage, but also because being done at a period when the conditions for the establishment of an efficient collateral circulation are bad gangrene is frequent. This has been a common result in the limbs, and no more striking example could be given than that of a surgeon in the Manchurian campaign who saw cerebral softening follow three times consecutively after ligaturing the common carotid in healthy young soldiers.

Secondary Operations.

3. Secondary operations may be undertaken at an average period of about four weeks, and practically resolve themselves into operations for aneurysms of three varieties. Each of the five methods of treatment may offer advantages under certain conditions which may be shortly stated:—

(*a*) *Simple ligature.*—Simple proximal ligature as near the aneurysmal sac as practicable has shown itself a satisfactory method of treatment for traumatic arterial aneurysms. Under certain circumstances it is likely to be still employed, either in dealing with small aneurysms or in situations where direct treatment may necessitate a prolonged and serious operation, as in the case of the carotid artery, especially when the conditions under which the operation has to be performed are not good.

(*b*) *Proximal and distal ligature, either of the artery alone or of both artery and vein.*—This method is suitable to the treatment of either arterial or arterio-venous aneurysms. Ligature of the artery alone is unsuitable to arterio-venous aneurysms or varices where there is any likelihood of the sac being in part fed by a collateral branch. If such a branch does exist the thrill of the varix will continue, and this though not a serious accident is yet undesirable. The addition of double ligature of the vein has not proved disadvantageous.

(*c*) *Syme's modification of Antyllus's operation (the intrasaccular direct ligature of Kikuzi).*—This method is applicable especially to large arterial hæmatomata, but also to recent arterio-venous aneurysms in some instances. The short length of the artery included between the ligatures, the limited amount of dissection needed to expose the vessel, and the fact that in the limbs the operation may often be performed while the circulation is controlled by an Esmarch's tourniquet are manifest advantages. Moreover, the danger of overlooking the presence of small branches feeding the sac is avoided, and mere evacuation of the clot is substituted for the troublesome dissection required if the sac is to be extirpated. This method has much to recommend it as an operation in military surgery.

(*d*) *Extirpation of the sac with limited excision of the vessels in communication with it.*—This method is applicable to the case of all aneurysms of whatever variety, where the occlusion of the vessel is not of appreciable importance to the general nutrition of the limb; practically therefore to any vessels below the brachial in the upper and the popliteal in the lower extremity. It has proved itself a highly successful procedure elsewhere, but it necessitates an often prolonged and difficult dissection and offers no material advantage over the last operation.

(*e*) *Suture of the wounded vessel, with or without extirpation of the sac.*—The relative advantages to be obtained by this method have been already discussed. If successful the result is ideal; it has not been shown to be attended by any accident to which other procedures are not liable, while even if thrombosis occurs and robs the operation of its crucial advantage the patient is not worse off than if ligature had been performed. Theoretically its applicability to the treatment of any of the forms of aneurysm is limited only by a lesion the situation or the extent of which prevents accurate and secure apposition, and even this difficulty is to be overcome by the insertion of an autoplastic graft from a neighbouring vein. Again, in certain situations, such as the neck, it obviates a risk of irrecoverable damage to the brain. Practically, however, the necessity of an aseptic field of operation, the existence of perfect operative surroundings, and a really high standard of manipulative skill on the part of the surgeon, must at present considerably limit its adoption in the routine of military surgery. If adopted, the operative technique devised by Carrel appears to offer the best chance of success. In old-standing cases of traumatic arterio-venous aneurysms, or aneurysmal varices Matas's arteriorrhaphy or the Matas-Bickham operation may be adopted.

Increased Conservatism.

A consideration of the wounds of arteries by bullets of small calibre and their treatment shows that progress in this branch of military surgery has taken the direction of increased conservatism and expectancy. In this it is no exception to that observed in every other chapter of the subject.

Non-interference in fractures has become almost the general rule, operations on joints have decreased in number almost to a vanishing point, injuries to the nerves are seldom the subjects of primary operative treatment, and we have seen that those of the vessels come into the same category.

Still more striking is the expectant attitude maintained by the surgeon in the case of wounds traversing the great body cavities, in all of which primary operations have become progressively fewer.

THE COLLET MEMORIAL, WORTHING.—At the Worthing Hospital on Dec. 5th a brass tablet was unveiled to the memory of Mr. A. H. Collet. Mr. Collet was an honorary medical officer of the institution from 1871 to 1909 and chairman of the committee of management 1908–09, and in appreciation of the great services rendered by him to the institution the sum of £337 8*s.* 6*d.* was collected, the bank interest swelling the sum to £359 14*s.* 8*d.* The memorial consists of complete X ray apparatus at a cost of £244 18*s.*, and the partial installation of the electric light throughout the building swallowed up the balance.

ON THE

DIAGNOSIS, PROGNOSIS, AND TREATMENT OF SYDENHAM'S CHOREA.[1]

BY FREDERICK LANGMEAD, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS TO ST. MARY'S HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

AMONG the many features of this disease I have ventured to select for special consideration its diagnosis, prognosis, and treatment, believing that their importance in practice will justify the choice, and knowing that you can all supplement my remarks by personal experiences, which I hope you will allow me to garner before the meeting ends. When the disease is well developed and exhibits the symptoms of its classical form, its recognition is attended with but little difficulty. The pseudo-purposive movements, grimacing, alteration in speech, and emotionalism make up a clinical picture which is usually distinctive. It is at its onset and at its close that doubt is most likely to arise.

Diagnosis.

Attacks of chorea have very small beginnings, and it is by no means easy to fix the time of onset of the malady. The choreic child is often highly strung, easily frightened, and as easily elated; one who is subject to night terrors, is afraid of the dark, and very imaginative. She is wont to people the darkness of her bedroom with the products of her active brain or the evil characters of her stories, for she is often a voracious reader. The early phases of chorea are marked by an exaggeration of this state, or by what may be called a condition of "psychical unrest." The child begins to get out of the control of her parents or teachers. She is inattentive in class, forgetful, and disobedient. Her powers of concentration lessen, and her brains go wool-gathering on the slightest provocation; every little occurrence diverts her mind. Her school work deteriorates, the shortcomings being particularly noticeable in arithmetic and writing. Her sums are all wrong; her figures and letters are badly formed, irregularly spaced, and sloping at various angles. This change in writing and arithmetic may often be noticed some weeks before erratic movements are obvious. What wonder, then, that her teacher sometimes metes out a punishment which he believes to be condign, but which so accentuates the attack as to make it obvious? What wonder, also, that the parents frequently ascribe the malady to admonition or punishment at school? At home a like fate may await her, for the mother often makes long complaint when the child is first brought for treatment, that she has been spiteful, mischievous, irritable, and sulky—indeed, that she can "do nothing with her."

The question arises, "How much nearer to the truth can *we* get by a medical examination than the parent or the teacher?" A little fidgetiness or a little grimacing may put us on our guard. The movements may need to be looked for. If the child be told to put her hands out straight in front of her, the arms outstretched, a little involuntary movement of the fingers may be detected; if at the same time she be asked questions or induced to repeat the alphabet or some simple verse, the movements may be more active, and twitchings of doubtful import may become more distinctive. Slight evidences of muscular weakness may be noticed also, "wrist-drop" may appear, the head may fall forwards, and the shoulders stoop. The weight of the body may be frequently changed from one leg to the other. Perhaps movement of the lips or tongue may evoke clucking or chirping noises, which are quite characteristic.

Examination of the heart may reveal slight abnormalities. It may be rapid or irregular, and the first sound may be short, sharp, and resembling the second. Perhaps a systolic murmur is audible, or a so-called reduplication of the second sound at the apex. The dulness may be slightly increased. If rheumatism has previously damaged the organ, signs of this may, of course, be present. At this stage the eye phenomena which I have described may help considerably in the diagnosis, for they often appear before the disease is well developed. They relate to the pupils. These may be unequal in size, to become equal again when the attack is over. The larger pupil may react to light and to accommodation more slowly than its fellow, and shows a greater feebleness in its reaction, perhaps remaining stationary or even dilating again whilst the other is still contracting. As well as change in size and change in reaction there may be also change in shape, one or more pupils becoming ovoid or irregular during the attack. Eccentricity may be noticed, both pupils or one ceasing to occupy the centre position and travelling still further afield when they react. Perhaps the most characteristic eye phenomenon is hippus, the pupillary margin of the iris oscillating backwards and forwards when accommodation is attempted or a light shone into the eyes. These ocular signs are by no means always present, but if obtained they bear out the inferences which have been made from the slight fidgeting movements, the slight signs of weakness, the psychical disturbances, and the early cardiac manifestations.

There is a form of chorea in which these mild symptoms are found alone and which may never develop into a more definite attack. This "latent" chorea, as Miller has called it, is often overlooked. It may be present for many months either between more serious attacks or quite independently. As means to a diagnosis the family history should be taken into consideration, and any personal history of rheumatism. It must not be forgotten that the evidences of rheumatism in such cases may have been very slight, and if considered alone, of doubtful value, but together provide ample corroboration. Such are joint and muscular pain and stiffness, sore-throats, anæmia, epistaxis, headaches, and epigastric pain.

When the disease is more developed and the characteristic movements are patent to all who look, perhaps there is no condition for which it is so often mistaken as tic, or, as it is more commonly called in children, "habit spasm." No doubt the confusion in terminology has done a good deal to foster this misapprehension, for chorea gravis is not what we now call chorea, but a complex form of tic, and St. Vitus's dance is a name which has been used indiscriminately for both conditions. In straightforward cases, I think, there should be little difficulty in making the distinction. The movements are dissimilar, for whilst in tic there is a continual repetition of the same movements, no matter how complicated they may be, in chorea it is impossible to anticipate what the next action will be. There is no regular sequence

[1] A paper read before the South-West London Medical Society on Nov. 12th, 1913.

in their production and no limit to their variations. The same is true of the grimacing. In tic a single movement or series of movements, such as blinking the eyes, shaking the head, nodding, twitching the mouth, &c., is repeated again and again. In chorea the whole gamut of the emotions may be reflected in the face in ever-changing order. In some cases, however, more difficulty may be encountered. This is particularly so when chorea and tic are present at the same time, the chorea being slight. The tic may obscure the clinical picture and the associated chorea escape detection. This combination is not so very rare, for the same type of child is prone to both affections. Again, in "residual" chorea, when the active stage of the disease is over, the movements may gradually become automatic, and the choreic child become in very truth a *ticqueur*, entering upon a state of chorea-like automatism which may persist for years.

The involuntary "athetoid" movements sometimes seen in cases of cerebral diplegia may be confused with those of chorea, but here the stiffness of the limbs, the exaggerated reflexes, the extensor plantar responses, the history and possibly the mental condition soon serve to put one on the right track. I have known meningitis and encephalitis in the early stage mistaken for chorea by very competent observers. When the vertex of the brain is primarily affected the convulsive movements of cortical irritation may very closely resemble those of severe chorea, but time soon corrects one's early impressions, bringing, as it does in the former case, rigidity, deepening unconsciousness, cranial nerve paralysis, optic neuritis, and the whole symptom-complex of meningitis. If it is important to dispel doubt quickly lumbar puncture will complete the diagnosis.

The paralytic form may escape recognition if the case is not seen in the early stages. After a period, during which the usual choreic movements have been present, the child lies helpless, unable to move her limbs, to lift up her head or to change her position. Aphasia is usually present, and there may be incontinence of urine and fæces. By no means under her control is she able to signify her wants. If she is lifted out of bed the limbs fall down and the head drops back much as occurs in early infancy. The muscles are very soft and flabby, so that the name "chorea mollis" is sometimes given to this form. The knee-jerks and other tendon reflexes are usually absent. The condition may persist for months. In such cases the diagnosis from some form of toxic neuritis has to be made. A history of previous choreic movements is of great value. Even when the paralysis is marked, by exceptional exertion some erratic movements of the hands may be recognised, whilst grimacing is not usually in complete abeyance. The presence of aphasia aids the diagnosis, and also the absence of loss of sensation, whilst the feel of the muscles is very characteristic. From diphtheritic paralysis the case may be diagnosed by the absence of ocular, palatal, intercostal, or diaphragmatic paralysis. In the paralytic form the degree of toxæmia may be very great, and the appearance of the patient may almost suggest that of typhoid fever. There may be much prostration, a very coated tongue, sordes on the lips and tongue, mental derangement, perhaps accompanied by hallucinations, and a considerable degree of fever. Here, again, the history of previous choreiform movements and their persistence to a very slight degree will usually serve to establish the diagnosis. The curious cry of chorea—like that of an animal—may recur again and again.

Prognosis.

It is generally agreed that the prognosis of chorea is very favourable, although it is impossible to fix the probable duration of an attack with any degree of precision. Six weeks is often held to be the minimal time during which it continues, but this, I think, is too short in the majority of cases and takes no account of the initial period before the symptoms are well marked. The most severe cases often terminate the most abruptly, and those with an extreme degree of movement frequently return to complete health in a much shorter time than others of very moderate severity. The paralytic and toxic types are apt to be long drawn out, but recovery almost always follows in the end, despite the serious nature of the condition. The latent form is liable to persist for months, the even tenour of its way being broken by more definite attacks. Death by exhaustion is a rare occurrence in the cases associated with a very marked degree of movement. Perhaps the two most important questions to ask in such cases are with regard to sleep and feeding. As long as the child is sleeping well, and can be fed naturally, no untoward result need be feared. In the rare cases where serious cardiac disease, such as myocarditis or pericarditis, accompanies the chorea the outlook is very grave. Speaking generally, the condition is serious, not from its immediate danger to life, but because of its rheumatic origin, its chronicity, and its tendency to recur. In this way it interferes greatly with school life, hampers education, and keeps the child below the standard of her fellows, although she is often endowed with more than the average number of talents. Valvular disease may start insidiously, and is often of a slowly progressive form, bringing with it the probability of repeated cardiac failure and chronic invalidism in later life. Poynton has remarked the particular association of chorea with persistent tachycardia and a progressive mitral stenosis.

Treatment.

The essential part of treatment during the active stage is *rest* both for the body and for the mind. The child should be put to bed in a quiet room, preferably darkened. When other children are treated in the same ward screening is distinctly advantageous. If the movements are so severe that the child is in danger of hitting and bruising herself or of falling out of bed, the sides of the bed should be raised and padded. Failing this, it is wise to make up a bed of considerable dimensions on the floor. All sources of excitement should be prohibited, and visits of friends and relatives should be avoided as far as possible. It is easily observed in hospital practice that on visiting day the distress caused by the arrival and departure of the relatives is followed by a period of enhanced excitability, and any entertainment, such as a birthday party or Christmas tree, has a similar effect.

Diet.

There is no need to restrict the diet; the appetite is usually good and food is taken readily. It must be given in fluid or semi-solid form, however, for mastication is far from easy, and meat, if not minced finely or pulped, is apt to be swallowed in large indigestible lumps. In more severe cases

swallowing may be difficult, and food in jelly form is more suitable. Such are firm custards, jellies (in which pulped meat may be suspended), junkets, &c. In the worst cases it may be necessary to feed by a nasal or œsophageal tube.

Medicinal.

I do not recognise a specific remedy in the treatment of chorea. I think you will agree that we have all seen cases which appeared to react quickly to a particular drug, whilst other cases apparently analogous were uninfluenced by it. In some cases after a short rest in bed the symptoms rapidly and unexpectedly subside; in others, apparently similar, the chorea persists in spite of the use of several therapeutic agents. There is a logical basis for the administration of sodium salicylate or aspirin because of their effect upon rheumatism—and we most of us regard chorea as a rheumatic manifestation; but, again, it must be confessed that in following a long series of cases treated in this way it is difficult to be sure that these drugs are capable either of diminishing the severity of an attack or of shortening its duration. However, I usually prescribe one of these drugs, for they are accredited with striking at the root of the disorder—namely, rheumatism—and by their administration one may hope to ward off further rheumatic manifestations. They are especially indicated if the temperature is raised, and should be pushed in sufficient doses to bring it down to normal. Dr. D. B. Lees advises that 400 to 500 grains of sodium salicylate should be given in 24 hours, and has himself given even more. Speaking with all due deference, I cannot say that I have found that these large doses have a better effect than others of more moderate size. If salicylates are used, whether in large or small doses, certain precautions should be taken to avoid poisoning symptoms. Those which are most to be feared are due to acid-intoxication, and resemble somewhat diabetic coma. The child becomes drowsy, her respirations deep and noisy (air hunger), vomiting occurs, the breath is sweet from the presence of acetone, and acetone and diacetic acid are found in the urine. If the salicylate is not discontinued the child may sink into coma and die, though this is a very rare occurrence.

These symptoms may be avoided if two precautions are exercised—first, the bowels should always be kept well open; and, secondly, twice as much sodium bicarbonate should be given as sodium salicylate. Before beginning salicylate treatment it is well to administer a purgative, and the bowels should have been opened within the 12 hours preceding any increase in the dose. By attention to these details all anxiety concerning acid-intoxication disappears.

Arsenic is perhaps the drug which is used next most frequently in the treatment of this condition, and some authorities state that it should be pressed until symptoms of arsenical poison supervene. There are two ways in which it is usually given—one in very large doses for a short time, until toxic symptoms arise, and the other in smaller doses for longer periods. I cannot say that I have been impressed by the value of the drug, whilst it has been my unfortunate experience to encounter more than one case in which arsenical neuritis was produced—a condition which takes far longer to get well than that for which the drug was given.

During the time that I was medical registrar at the Hospital for Sick Children, Great Ormond-street, I had the opportunity of watching the effect of treatment by drugs on chorea. In one ward very large doses of sodium salicylate were being given in every case. In another arsenic was extensively tried, whilst in a third no drug treatment was relied upon, and many of the patients received no so-called specific for the disease. Two years' observation of the cases in the different wards failed to convince me that the patients improved more rapidly in one than in another, and, indeed, some of the most satisfactory cases were those in which no special drug took any part in the treatment. Chloral and bromides are particularly useful where there is loss of sleep, and have a very special indication in those patients who, with extremely active movements, begin to show signs of exhaustion from loss of sleep. When used for these particular cases I believe that sedatives, of which these two are examples, are of great value. Another measure of great assistance in such cases is the hot pack.

I have been able to watch the effects of treatment by chloretone, a drug which has been advocated strongly by Dr. Essex Wynter for this condition. Again, I must confess to a failure to recognise any great advantages accruing. If the drug is pushed the children become very drowsy, and no doubt movements are less as the result; but it is questionable whether the good effects warrant this procedure except in cases of great loss of sleep, such as those which react to other nerve sedatives and the hot pack. Ergot has been recommended by Dr. Eustace Smith. My experience of it is very limited, but as far as it goes it agrees with that of others who have written on the subject, and who have been unable to obtain his good results.

After-Treatment.

The after-treatment of chorea is almost as important as the treatment of the acute attack. There comes a time when the active stage is over, but the child lies in a listless state with general muscular feebleness and perhaps slight movements. Further rest in bed produces no improvement. At this stage it is advisable to encourage the child to perform voluntary movements and to re educate its coördination. Massage and passive movements also play a useful part at this time. Many simple devices may be employed to re-establish coördinated movements.

At the beginning of this form of treatment such simple exercises as apposing the corresponding fingers of the two hands or touching the nose with each finger in succession are useful. While the patient is still in bed the following exercise may be used: heel to toe, heel to shin, heel to knee, first with one leg and then with the other. Afterwards somewhat more complicated movements may gradually be introduced, such as placing a cribbage-peg into every second, every third, or every fourth hole, games of draughts, halma, dominoes, and the like. When the patient is out of bed coördination of the legs may be re-educated by getting her to walk along a straight line, on chalk dots, or on certain parts of the pattern of the carpet. These are only a few examples of many exercises which may be devised with a little ingenuity. By such means the period of convalescence may be shortened materially, and the incidence of residual chorea and choreiform automatism considerably diminished.

Queen Anne-street, W.

OIL-ETHER ANÆSTHESIA.[1]

BY J. T. GWATHMEY, M.D.

OIL-ETHER colonic anæsthesia is an evolution from intravenous anæsthesia. In developing the technique, however, full advantage has been taken of all that has been written on rectal anæsthesia, as revived by Cunningham, of Boston, and continued by Sutton, of Kansas City, when an interne at Roosevelt Hospital. The animal work under the direction of Professor Wallace in the pharmacological laboratory of New York University and Bellevue Medical College has already been reported. Carron oil has been discarded entirely, and olive oil is now used exclusively, the resulting anæsthesia not being followed in any case by diarrhœa or bloody stools. The cases in which olive oil was used seemed to have less nausea and vomiting than those in which other oils were used. This verifies the work of Graham relative to restoration of the opsonic index by the absorption of olive oil into the system after operation.[2]

The advantages claimed for this method of anæsthesia are: (1) The element of apprehension and fear caused by placing a mask over the face is avoided; (2) no expensive apparatus is required; (3) the after-effects are reduced to a minimum; (4) a more complete relaxation is secured than with any other known method; (5) the limits of safety are widely extended compared with other methods; and (6) a more even plane of surgical anæsthesia is automatically maintained than is possible by any inhalation method—unless administered by a skilled anæsthetist using a perfected apparatus.

These propositions have been demonstrated in about 100 cases, the ages ranging from 4 to 71 years. In all the cases the operations have been witnessed by members of the profession, in one instance by 40 physicians and surgeons. In most cases careful blood and urine analyses were made before and after operation. The blood pressure was taken during the operation. Some of the patients were also carefully examined with the proctoscope to note if any inflammatory disturbances followed. None of these examinations showed any contraindications. Patients who had been previously anæsthetised by other methods expressed themselves most enthusiastically in its favour.

Reports of Cases.

The following cases illustrate the dangers to be avoided and the doses to be employed:—

CASE 1.—Boy, aged 10 years; operation for hydrocele and circumcision. Sulphate of morphine, 1/12 grain, was given hypodermically 30 minutes before the operation, and also a 5 grain chloretone suppository; 75-100 c.c. of a 75 per cent. mixture were introduced very slowly, the patient falling asleep before the full amount was introduced, sleeping quietly through the operation, and making an uneventful recovery.

CASE 2.—In a girl, 9 years of age, 100 c.c. of a 75 per cent. solution were given with no preliminary medication. The child complained slightly as the mixture was administered. The operation was for adenoids and enlarged tonsils. The relaxation was perfect, and she left the hospital five hours after the operation.

In children aged 4 to 8 years a 50 or 55 per cent. solution of ether in olive oil has been easily retained, without any preliminary medication, and has been followed by satisfactory anæsthesia in 10 to 20 minutes. In adults 8 ounces of ether, with an equal amount of oil, were placed in the rectum with no anæsthetic effect whatever.

Several other cases of different operations on children have been reported by different surgeons, who expressed themselves unqualifiedly in favour of this method of anæsthesia.

CASE 3.—On Nov. 18th a woman, aged 38 years, weight 125 lb., was operated upon at the Presbyterian Hospital by Dr. Forbes Hawkes for carcinoma of the breast. She was given 1/6 grain of morphine and 1/100 grain of atropine hypodermically; 5 grains of chloretone, dissolved in 2 drachms of ether and mixed with 2 drachms of olive oil, were introduced into the rectum 30 minutes before the operation. Eight ounces of a 75 per cent. mixture were introduced into the rectum in six minutes' time. The patient was in surgical anæsthesia four minutes after the total mixture had been introduced. Three ounces were drawn off during the operation, as the patient seemed too deeply narcotised. The anæsthesia was perfect in every respect, the patient breathing quietly as in natural sleep during the entire operation. An uneventful recovery with no nausea or vomiting followed. Blood and urine analyses proved negative.

A similar case was operated on by Dr. Cantle at the New Rochelle Hospital with equally gratifying results. In this instance no suppository was used, and there was a slight complaint of discomfort in the rectum as the mixture was introduced. The patient, who had been operated upon twice previously under inhalation methods, stated that if compelled to undergo another operation the oil-ether would be the choice of methods. The former patient did not complain or in any way show that the introduction of the mixture was appreciable, this freedom from discomfort being, in the author's opinion, entirely accounted for by the administration of the chloretone.

CASE 4.—Operation for abdominal hernia by Dr. Bodine at the New York Polyclinic Hospital. The patient, a woman aged 37 years, weight about 150 lb., was given ¼ grain of morphine and 1/150 grain of atropine 30 minutes before the operation. At the same time a solution containing 10 grains of chloretone and 4 drachms of ether with an equal amount of olive oil was introduced into the rectum. Just before operation 8 ounces of a 75 per cent. solution were given to the patient in bed. She sank into deep surgical narcosis before the full amount (8 ounces) was introduced. A slight cyanosis indicated an overdose, therefore 3½ ounces were drawn off, as the patient was placed upon the operating table. The relaxation in this instance was perfect; pulse and respiration were about normal. The patient slept for six hours after completion of the operation and awoke without nausea or vomiting, in a perfectly satisfactory state in every respect.

Watchfulness must be exercised at all times, as in other anæsthesias, the chief danger being respiratory arrest, as shown in the following cases:—

CASE 5.—A woman weighing less than 100 lb., about 30 years of age, was operated upon for pelvic cellulitis. She was given ¼ grain of morphine and 1/150 grain of atropine hypodermically, and a suppository containing 20 grains of chloretone as preliminary medication. Eight ounces of a 75 per cent. solution of ether in oil were given as the anæsthetic. This patient evidently received an overdose of preliminary medication, also of the anæsthetic. Respiratory arrest occurred a few minutes after she was placed upon the operating table. Artificial respiration, stretching of the sphincter, and the intravenous introduction of 1000 c.c. of normal saline were employed. A bag containing a small amount of carbon dioxide was then placed over her face, whereupon respiration recommenced immediately. During the time of this respiratory arrest, which, according to the operating nurse, lasted eight minutes, the pulse was full, regular, and approximately normal. The colour of the lips

[1] Being an abstract of a paper read before the New York Society of Anæsthetists on Nov. 20th, 1913.

[2] Graham: Journal of the American Medical Association, March 26th, 1910, p. 1043.

and tongue was good. The operation was satisfactorily performed and the patient was returned to bed. An uneventful recovery is recorded in this instance, with no nausea, vomiting, or other ill-effects.

In a case of excision of the tongue, floor of the mouth, and glands of the neck for concerous growth the operation lasted nearly three hours. At the end of one hour there was stertor which perceptibly increased until respiration ceased for three minutes. The rectum was washed out with cold water, and as much as possible of the mixture was withdrawn. Respiration recommenced without anything else being done, and the operation was completed without further interruption. An inhalation anæsthetic would have undoubtedly increased the engorgement and congestion usually following such cases. This case illustrates that if stertor occurs and the reflexes become dull (especially the lid reflex), it is an indication of an overdose and the rectum should be immediately washed out and one or two ounces of oil introduced.

No deaths can properly be credited to this method, although one patient succumbed within 24 hours after having fully recovered from the anæsthetic. In the opinion of the surgeon and the coroner the conditions found post mortem fully accounted for the death. At the commencement of the series in two instances unpleasant symptoms occurred on the introduction of the anæsthetic, and a supplementary anæsthetic was required. These patients received the anæsthetic in the dorsal position, which has since been abandoned. With improvements in technique no untoward incidents or failures have been recorded.

Physiology.—Indications and Contraindications.

The breathing in all instances is perfectly normal. If stertor commences it indicates unnecessary deepening of the anæsthesia. Cyanosis should not occur; if present it indicates an unnecessary depth of anæsthesia. The reflexes are quite active, especially the lid reflex. The pulse is normal, or only slightly accelerated, depending upon the preliminary medication. The face is never flushed, as with ether given by inhalation.

All these conditions result from the method of introduction. As the ether separates from the oil after its introduction it assumes the form of a gas and is taken up by the blood. It then passes through the lungs, where a part is excreted; the remainder is immediately resorbed, and thence reaches the brain. As a large quantity is lost by exhalation, the brain is never so deeply narcotised as when the anæsthetic is administered by inhalation, this probably accounting for the wide latitude of safety.

In inhalation methods the higher centres of the brain are first affected. The first symptom noticed by patients in the oil-ether colonic method is loss of sensation in the lower extremities, showing a sensory paralysis, first of the extremities, the higher centres of the brain being the last affected. This observation seems to be verified by the fact that consciousness is regained long before the sensations of pain are manifested. This last observation opens up a wide field for investigation and research, since we now know that ether can be introduced into the system without its nauseating effects being manifested. In a 50 or 60 per cent. solution it may be administered for the relief of pain, just as we would use a hypodermic injection of morphine, with the same degree of assurance and without the possibility of an injurious habit being acquired.

The method is especially indicated in bronchoscopic work and in operations upon the head and trunk; also in cases of Graves's disease and similar conditions where the element of fear is a dominant factor. It has been demonstrated conclusively that we can administer it with confidence to those patients who have suffered much nausea and vomiting from the previous administration of ether anæsthesia. It may be positively asserted that the ether is not so irritating when given in this way as by the usual inhalation method. It has been given to a consumptive having hæmorrhages from the lungs, at irregular intervals, with no deleterious effects.

If these facts are borne in mind to modify our conclusions we may state that it would be contraindicated in most cases where ether is contraindicated; also in colitis, hæmorrhoids, fistula in ano, or other pathological conditions of the lower bowel. Even where no pathological condition exists, if the patient complains upon its introduction, this would also be a contraindication.

Combined Methods.

Those who are wedded to either spinal or intravenous anæsthesia will welcome oil-ether as fulfilling all the requirements of these methods without the possibilities of infection or other serious trouble. The combined method, as I have outlined it, will also attract those who wish for such simplicity of administration and directness as is afforded by the drop method of ether anæsthesia. Nitrous oxide and oxygen can be administered in a much greater number of cases with fewer possibilities of discomfort when used in combination with one-half of the oil-ether mixture required for full anæsthesia. The relaxation obtained is more satisfactory than with nitrous oxide, oxygen, and ether given by inhalation. For endotracheal anæsthesia, in addition to the oil-ether in the rectum, any pump that will deliver sufficient air to maintain the necessary positive pressure in the lungs will be the only apparatus needed.

I particularly wish to emphasise, however, that the combination of oil and ether can be safely introduced into the system and that the anæsthetic is always under control. The reasons for this are: (1) The anæsthesia is automatically safeguarded by the gradual and equal absorption of the ether from the colon and at the same time its rapid evaporation from the lungs; (2) the affinity of the oil and ether for each other.

In a former paper I stated that "to a practitioner compelled to work alone this method would be of inestimable benefit." From experience I find that for a practitioner so circumstanced a 55 to 65 per cent. solution of ether and oil would be safer, allowing 15 or 20 minutes for the mixture to have its full physiological effect and then supplementing this, if necessary, with a few drops of ether on a mask. This would be better than getting the patient deeply under with a 75 per cent. solution, possibly having to withdraw some of the mixture if the patient was too deeply narcotised. This combined method would also apply to hospital internes and others who have not had extensive experience with anæsthetics. To anyone compelled by circumstances to place the narcosis in the hands of a layman or one unskilled, this combined method would be safer than inhalation anæsthesia exclusively.

Percentages and Amounts Employed.

In using the oil-ether method alone, the anæsthetist must have well in mind the physiology, as

outlined above, in order to avoid mistakes. The following rough outline will aid in deciding upon the percentages and amounts to be used. For children under 6 years of age a 50 per cent. solution should be employed, allowing 1 ounce for every 20 lb. of body weight; this mixture is non-irritating, and no preliminary medication is required. For patients from 6 to 12 years of age, use a 55 to 65 per cent. solution, without preliminary medication, keeping the patient quiet, and allowing 20 to 30 minutes for the full effect; allow 1 ounce for every 20 lb. of body weight, as before. For patients from 12 to 15 years of age, use the same percentages and amounts, with possibly the addition of 1/12 grain of morphine and 1/200 grain of atropine, given hypodermically as a preliminary. From 15 years upward a 75 per cent. mixture is employed, the amount and preliminary medication varying with the size and general condition of the patient, and the same rule being followed as to quantity—that is, 1 ounce for every 20 lb. of body weight. Thus we see, for an adult weighing about 160 lb., 8 oz. would be required. This represents the usual dose for the average patient.

The administration of any preliminary medication will always vary, depending largely upon the opinion of the surgeon or anæsthetist. For adults I usually employ 5 grains of chloretone, dissolved in 2 drachms of ether and mixed with an equal amount of olive oil, given per rectum 30 minutes before the operation. In addition to this $\frac{1}{6}$ to $\frac{1}{4}$ grain of morphine, with 1/100 grain of atropine, is given hypodermically at the same time—the larger doses being given only to athletes and alcoholics.

Technique and Apparatus.

The patient should receive the usual medication as for any operation, avoiding purging. In addition, the colon should be thoroughly irrigated until the return is clear. A rest in bed of two hours or more before the preliminary medication is required.

The apparatus required is very simple—a small catheter and funnel, two small rectal catheters inserted side by side, and a towel placed over the face from time to time to prevent the dilution of the anæsthetic in the air passages. When the patient is satisfactorily narcotised the towel is withdrawn.

The mixture (2 ounces of olive oil and 6 ounces of ether) is given with the patient in bed on the left side, in the Sims position, a convenient lifter having previously been placed under him. It is not always necessary that he should know that an anæsthetic is being administered. A small catheter, well lubricated, is then inserted 3 to 4 inches within the rectum; to this catheter a funnel is attached. The mixture should be poured slowly into the funnel, taking at least 5 minutes for 8 ounces, the usual amount. It is best not to withdraw the tube until the patient is partly unconscious and the muscles are relaxed. From 5 to 20 minutes (according to the percentage used) should be allowed for the anæsthetic to take effect before the patient is moved. The patient should then be lifted gently on a stretcher and carried to the operating-room. The anæsthetist at this time should see that a clear airway is maintained when necessary by placing a finger under the symphysis of the lower jaw. If the patient shows signs of approaching cyanosis, loss of lid reflex, stertor, or embarrassed respiration of any kind, 2 or 3 ounces of the mixture should be withdrawn by the small rectal tube placed 4 to 6 inches up the rectum. If the breathing is easy and regular, with the reflexes active, the patient will be found to be relaxed and in surgical narcosis as far as the operation is concerned.

At the end of the operation the two small rectal tubes should be placed in position, as high up the colon as convenient without traumatism, and cold water soapsuds injected into one tube and drawn off through the other; 2 to 4 ounces of olive oil should then be introduced into the rectum and the tubes withdrawn. The patient should be gently returned to bed, with as little jolting or handling as possible, the room should be darkened, and free ventilation secured.

In some of the cases novocaine was injected locally at the site of the operation after the patient came on the operating table; in other cases no local anæsthetic was used. Where this is done and the oil-ether rectal method is used as outlined every principle of anoci-association as enunciated by Crile[3] will be fulfilled, and the patient awakes quietly, without nausea, vomiting, or pain, the analgesia continuing for some time after consciousness is restored.

New York.

DEVELOPMENT OF THE PHARYNX BY MUSCULAR EXERCISES AFTER OPERATION FOR ADENOIDS,

WITH SPECIAL REFERENCE TO FEEBLE-MINDED CHILDREN.

BY FRANCIS WARNER, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND LECTURER ON THE NEUROSES AND PSYCHOSES OF CHILDREN.

IN children with adenoids and naso-pharyngeal obstruction, when a digital examination is made the pharynx is usually found to be small, and this interferes with respiration, deglutition, and good speech; this condition is specially frequent in the small-headed children so commonly seen among the feeble-minded. During the last two or three years I have used exercises of the pterygoid muscles for the purpose of developing the bony boundaries of the pharynx with favourable results; the strength of the jaw movements has certainly become stronger; in each case deglutition and speech have somewhat improved, and I think it likely there has been growth of the sphenoid bone with widening of the space between the pterygoid plates which form the lateral boundaries of the upper pharynx; but I know of no accurate gauge of the size of this space other than the finger.

When the finger is passed above the palate in examination for adenoids the pharynx is often found to be small. This space is bounded behind by the basilar process of the occipital bone, with the body of the sphenoid, and laterally by the internal plates of the pterygoid processes and the hamular processes; the dimensions of this space increase with growth of the sphenoid as a whole. The muscles arising from these pterygoid bones are of considerable strength, and are inserted into the lower jaw, producing by their action lateral movements of the chin and protrusion and retraction of the lower jaw; their action (when in tension) affords a stimulus to the growth both of the sphenoid and inferior maxilla. The sphenoid in

[3] THE LANCET, July 5th, 1913, p. 7

the normal continues to grow till about the tenth year.

When the adenoid growths have been removed and the respiratory passages are clear, after convalescence useful exercises may be taught by a teacher, under the medical man's directions, to work the pterygoid and other jaw muscles. The chin should be held firmly by the teacher's fingers to prevent its movement and produce muscular tension, while the teeth are slightly separated; the pupil is then told to try to press his chin to the right, then to the left, when the effect of muscular action is indicated by the pressure produced. The jaw may next be pressed forward, as in protruding the teeth, then retracted. These exercises may be followed by downward pressure of the jaw against the teacher's hand, and clinching the teeth or biting on a piece of indiarubber, till the temporal and masseter muscles are felt to harden. Such exercises may be repeated half a dozen times. If action of the facial muscles is avoided with these exercises, and the chin is held firmly, I have not found that they cause grimaces or tooth grinding.

After the exercises have been taught by the teacher for a sufficient time it is usually better to hand over the work to the drill instructor; as the muscular power of the jaw movements grows stronger a corresponding strength of hand is needed in holding the chin firmly so as to insure pressure without movement of the jaw. Such exercises in many cases may be continued for a year or two. It is often useful to have these exercises along with other gymnastic teaching so as to obtain the pupil's best energy. The principal means at our disposal for stimulating the growth of a bone is by exercising the muscles attached thereto. I do not know of any more feasible plan of encouraging growth of the sphenoid and the development of a wider pharynx than the exercises described.

After adenoid operation it is desirable to train the child to breathe through the nose with the lips closed, but breathing exercises are also needed, especially for the feeble-minded. The child must be made to perform each of the movements of inspiration separately as well as to "breathe deeply." Here again I like daily exercises by the teacher as well as in the gymnasium. Movements of the chest should be made in three directions. With hands placed vertically on the front of the chest the teacher may tell the pupil to lift them up, feeling at the same time that the ribs are raised, and not be satisfied with a little hardening of the pectoral muscles. Then placing her hands so as to grasp the sides of the chest direct that they shall be moved outwards, causing lateral expansion. Lastly, getting the special uplifting of the first two ribs which can be felt under the collar bones, and move more freely than the lower ones. The diaphragm seems to be very little used by many feeble-minded children: to exercise this muscle let the pupil stand straight against a wall, and with a hand placed flat over the abdomen be told to press it forward in breathing. Excellent breathing exercises have been described by many writers, but the movements given are useful with all defective children.

The post-adenoid operation cases I have had to treat were mostly children, more or less feeble-minded, who require a great deal of training of the whole nerve-muscular system before good action is obtainable in hard muscular work. Organised lessons must be given daily in making coördinated movements, such as moving the eyes to look at what is shown, and in imitation at sight of teacher's hand and finger exercises made slowly and with precision as well as when told to perform them. Imitation of lip movements may be taught later. The "movement" must be learnt and practised before the action produces much muscle tension. This may be illustrated by exercises employed to strengthen the weak finger power so common in the defective child from want of development of the intrinsic muscles of the hand—viz., the interossei, lumbricals, and the thenar and hypothenar groups. First use exercises to control the movement produced by these muscles, later bring them into tension by making passive resistance to the finger movement with elastic bands, the use of weights, &c., which causes the muscles to harden. All this is useful mental training, producing coördination, good movements in response, and growth.

Small-headed children are often short, slightly built, and much under weight, consequently there is a less amount of physical work done when they move their limbs and walk than with others of normal growth. I usually begin muscular training by making the child lift weights in the hand, substituting ½-lb. wooden bricks for toy ones; let him carry books, bags of stones, &c., and in other ways produce muscular exercise as well as coördinated movements; thus we increase energy and voluntary power—it is often surprising to see how much hard work these children can do. Such muscular training continued systematically for two or three years affords the best stimulus I know of in promoting growth of brain and skull; in some cases the head circumference has grown from 18¾ inches at six years to 20 inches at nine years with corresponding growth of the pharynx and marked development of brain power.

London Hospital.

ON A FATAL CASE OF PELLAGRA IN AN INSANE PATIENT.

BY F. E. RAINSFORD, M.D. DUB.,

MEDICAL SUPERINTENDENT, STEWART INSTITUTION FOR IMBECILE CHILDREN AND HOSPITAL FOR MENTAL DISEASES, CHAPELIZOD, CO. DUBLIN.

THE case which I am about to report is interesting, inasmuch as it is, I think, the first recorded case of this disease in Ireland. Attention has recently been directed to the occurrence of cases of this disease in asylums in England, and it is owing to the information afforded by these reports that I was enabled to recognise the case in question.

The patient, a widow, aged about 70 years, was admitted to the Stewart Institution on July 3rd, 1913. The history given was that she had led rather a hard life, having been deserted by her husband early in her married life when in good circumstances, and had to bring up a young family with very limited means. She first broke down mentally in August, 1912, and was sent to a private asylum in September of that year, where she remained till May, 1913. She was then taken to her daughter's house, but there got very restless and excited and was inclined to wander. She developed delusions mainly of danger affecting her relatives, and finally got so bad that she was put under my care. On admission she was noted to be a woman of frail physique and worn aspect, and looking older than her years. Her bodily organs were healthy and she took nourishment well. Her mental condition was generally one of confusion

and dementia. She talked vaguely of the Germans and of the German Emperor, whom she thought was coming over to see her; of a green purse that had gone to heaven, and so forth. She settled down quietly for some days and seemed to improve, but on July 8th she got very restless and talked vaguely of lions, bears, and tigers, which frightened her. The next day she was much distressed, saying that a great gunpowder explosion had occurred near and she feared it had damaged her house and children; that the Germans had landed and that wagons of ammunition and cannons had gone along the road. Later she thought the house was going on fire and she tried to get out of the window. She was given trional, 20 gr. at bedtime, on one occasion and soon quieted down, and is noted on August 2nd to be much quieter and to be eating and sleeping well.

In or about the middle of August my attention was drawn to an erythematous rash of a crescentic shape situated in the middle of the forehead extending from the roots of the hair downwards, about 1½ inches in breadth at its widest part. It exactly resembled an acute sunburn, but the limited area affected negatived that in my mind. I confess I gave it little attention beyond directing the application of an emollient ointment. In a few days the hands became acutely inflamed, red and swollen, the inflammatory process involving all the backs of the hands and the wrists. They soon began to desquamate and got hard and scaly. The portion of the forehead first affected soon healed up, the healing process being accompanied by slight branny desquamation, the surface being coarse, harsh, and dry. Some small patches of inflammation were noticed in the angle of either eye and just below the margin of the lower eyelids. These latter patches never desquamated to any extent. On August 26th vomiting and diarrhœa were reported, which continued till the 30th, when treatment succeeded in checking both these symptoms.

Notwithstanding, the patient got rapidly worse, and on Sept. 2nd I note that she is "drowsy and dull, disinclined to eat, swallows with difficulty, and is in a semi-stuporose condition from which it is difficult to arouse her." On the 3rd muscular twitchings were noted and a tendency to stertor, so that I feared she would get an attack of cerebral hæmorrhage. The knee-jerks were absent and there was a general languor and prostration out of all proportion to the symptoms. Up to this I had not recognised the true nature of her affection, but an article which appeared in THE LANCET of Sept. 6th made it clear to me that I had to deal with a case of pellagra. I then asked Professor Walter Smith —our consulting physician—to see the case, and he agreed with me in regarding it as a case of pellagra. Dr. T. G. Moorhead, who also saw the case, concurred in the diagnosis. The patient rapidly got worse and died on Sept. 11th.

Just before her death my assistant, Dr. Kenneth Drury, kindly took some photographs to show the condition of her hands, but owing to the patient's very weak state and the deficient light in the room they are not very instructive. The condition of the hand just before death may be described as follows: colour purplish-brown, continuously affected on the extensor aspects, there being no patches of healthy skin; ends of fingers from roots of nails not affected (this is also noted in Dr. Cole's case). The skin feels rough and scaly, and there are patches of pigmentation, most marked on the wrists, deeper towards the carpal bones, and fading off as it extends towards the arm. The patch on the forehead, which had almost healed up before death, showed but little pigmentation, but there were isolated patches of dried-up secretion of a deep amber colour. There was never any œdema, and as far as could be ascertained the condition was painless.

It is abundantly clear that if we are to regard this as a case of pellagra we shall have to modify or completely re-arrange all the old teaching as to this disease. Dr. G. S. Blandy, of Napsbury Asylum, in THE LANCET of Sept. 6th, describes 11 cases of this condition, and Dr. J. W. E. Cole in the same issue describes a case in Bethnal House Asylum. In THE LANCET of Oct. 18th Dr. Emma M. Johnstone records three cases in the Holloway Sanatorium. All the cases recorded occurred in females, and in most instances their general health was poor. Most of them occurred in a year in which the heat was abnormal, though in most cases those affected were not exposed to the sun's rays. It is further interesting to note that all the cases so far recorded in England occurred in the insane. None of those affected seemed to have had maize as an article of diet. Dr. L. W. Sambon, who is investigating the disease, will doubtless in time be able to shed some light on this point, but so far the causation remains obscure.

THE USE OF VACCINES GRADUATED BY THEIR OPACITY.

BY LEWIS C. BRUCE, M.D. EDIN., F.R.C.P. EDIN.,
PHYSICIAN TO, AND SUPERINTENDENT OF, PERTH DISTRICT ASYLUM, MURTHLY.

For several years in the ordinary medical practice of the Perth District Asylum I have been in the habit of preparing the necessary vaccines for the treatment of certain bacterial diseases and of graduating them by the method of counting the organisms. The results were satisfactory, but the labour was considerable. Latterly I have graduated the vaccines by their opacity; the results of treatment have been equally satisfactory, and the labour has been reduced to a minimum.

My method is to grow the cultures on agar, blood agar, &c., and to make an emulsion of the growth with normal saline. The emulsion is then placed in a 5/8th in. test-tube and diluted with normal saline until is is possible to read clearly certain type through the medium of the tube containing the emulsion. The type I employ as a meter is the ordinary type of Muir and Ritchie's Handbook. The vaccine is then sterilised by heat or it is sterilised by chloroform or by ether. Satisfactory results were obtained by all three methods of sterilisation. If the vaccine is to be used by myself I use it in the above density, making the initial dose in every case 0·1 c.c. If the vaccine is to be used by a general practitioner I dilute the original emulsion to 2½ or 5 volumes, and the dose will then be either 0·25 or 0·5 c.c. Subsequent doses can be increased or diminished according to the reaction obtained from the first injection.

In giving the injections in nervous patients I have found it useful to spray the skin at the point of the intended puncture with ethyl chloride. It is unnecessary to freeze the skin; the intense cold produced by a few seconds' application of the anæsthetic is sufficient to deaden completely the pain of the puncture.

I append a list of the results in 88 cases treated

by vaccines graduated in the manner above described.

Cases.	Disease.	Infection.	Remarks.
1 to 30	Boils, recurrent and multiple.	Staphylococcus aureus.	26 cases after two injections had no recurrences. Two relapsed, but after two more injections recovered. Two improved, but had frequent recurrences of boils; immunity induced by further injections of temporary nature.
31	Carbuncle of neck.	,,	No benefit from vaccine. The patient died from septicæmia.
32	Carbuncle of back.	,,	Marked improvement after one injection.
33 to 37	Impetigo contagiosa.	,,	Four cases free after two injections; 1 relapsed, but on reinjection recovered. Fifth case showed only temporary improvement to repeated injections.
38	Eczema of back of both hands.	Streptococcus.	For 3 years attacks recurred in spring and autumn. Two injections removed the condition; no recurrence for 3 years.
39 to 41	Malignant endocarditis.	,,	No improvement as the result of injections.
42	Chronic bronchitis.	Micrococcus catarrhalis.	Improvement, but not recovery after two injections.
43 to 50	Acute nasal catarrh.	,,	Marked relief and an average of 3 months' immunity after from one to three injections.
51 to 52	,,	Pneumococcus.	Marked relief in both after one injection.
53	Chronic nasal catarrh of several years' standing.	Mixed, micrococcus catarrhalis and bacillus prodigiosus.	No benefit after repeated injections.
54	Chronic nasal catarrh, two years, complicated by asthma.	Mixed, micrococcus catarrhalis and bacillus septicus.	No benefit after repeated injections.
56 to 67	Chronic nasal catarrhs, one year and one month.	Micrococcus catarrhalis.	Relief and recovery after from two to three injections in 10. No temporary or permanent benefit in the remaining 2 cases.
68 to 70	Cystitis.	Streptococcus.	Recovery after two injections.
71 to 75	,,	Bacillus coli.	Recovery after from three to five injections.
76	Cystitis with symptoms of pyelitis.	,,	After one injection temperature fell from 103° to 101° F. Recovery after two further injections.
77 to 79	Conjunctivitis with blepharitis (chronic).	Staphylococcus aureus.	Relief after two injections, lids remaining red and thickened.
80	Conjunctivitis, recurrent.	Bacillus (?)	One injection relieved symptoms; after two injections inflammation disappeared and no recurrence.
81	Chronic sinus of knee-joint after tuberculous disease.	Staphylococcus aureus.	The sinus healed after two injections.
82 to 85	Chronic sinuses, suppurating glands of neck.	,,	In 2 sinuses healed after one injection; 2 healed but broke down, requiring surgical treatment.
86	Chronic otitis media with frequently recurring abscesses.	Bacillus (?)	Marked relief after two injections. Patient passed out of my care.
87	Chronic sinus after removal of mastoid.	Staphylococcus aureus.	After six injections sinus healed; has remained so over a year.
88	Chronic ulcer of hand, the result of post-mortem infection.	Streptococcus.	Two injections removed a condition which lasted 3 months, resisting all local treatment.

Murthly.

LATIN-AMERICAN MEDICAL CONGRESS.—This Congress, held in Lima in November, was attended by a large number of eminent members of the profession, representing Argentina, Brazil, Chili, Paraguay, Uruguay, and of course Peru, and was a very successful meeting. The members were publicly entertained by the President of the Peruvian Republic, Mr. Billinghurst, and many papers of great public interest were read and discussed, amongst others one by Dr. Barboza, a Brazilian delegate, on the extensive sanitary measures which have been carried out in Rio de Janeiro.

CANCER OF THE TONGUE AND LARYNX REMOVED BY OPERATION.

BY W. S. KERR, M.B., C.M. EDIN., F.R.C.S. EDIN.,
SURGEON TO THE EAR AND THROAT DEPARTMENT OF THE SHEFFIELD ROYAL INFIRMARY.

THE desirability or otherwise of performing extensive and mutilating operations for cancer of the tongue and larynx is a question which invariably taxes the judgment of those who are called upon to treat the condition, and it constitutes my reason for publishing the following case.

The patient, a man, aged 45, had suffered from painful deglutition, pain in the ears, hoarseness, and rapid loss of weight and strength for about three months. His mouth and throat were very intolerant of examination either by the indirect or direct method, but the epiglottis could be seen as a fungating, ulcerating mass, with a broad, ulcerated base involving the root of the tongue and the superior aperture of the larynx. A small portion removed by punch forceps was pronounced to be definitely epitheliomatous. No enlarged glands could be palpated in the neck. The condition, together with the reasons for and against operation, were explained to the patient, and he decided for operation.

The mouth and teeth were carefully cleansed for several days before the operation, which was performed on Sept. 8th, 1913. A tracheotomy through the tied and divided thyroid isthmus was first performed and a Hahn's tube introduced. Both external carotids with their superior thyroid and lingual branches were ligatured through the usual incisions. The attachments of the tongue to the floor of the mouth were then divided by scissors down to the hyoid bone, which was divided in the middle line and the halves widely separated. The front and sides of the larynx and thyro-hyoid membrane had been previously cleared, the incision being carried up above the hyoid into the floor of the mouth. The tongue was brought out through this incision, and the consequent free exposure of the superior aperture of the larynx showed an infiltrating growth especially affecting the right side of the larynx. The cords were healthy. The mucous membrane of the pharynx was divided transversely at the upper border of the cricoid and the tongue and larynx above the cricoid were removed in one mass. The cricoid was left in position, as it made an admirable opening for stitching to the skin of the neck. The hæmorrhage during the operation was practically *nil*. The mucous membrane on the posterior surface of the cricoid was freed and stitched up to the remains of the structures in the floor of the mouth. An œsophageal tube was passed and left *in situ*. The wound in the neck was left open, the tracheotomy tube being removed.

The patient did well for a few days, taking his food through the tube and getting a fair amount of sleep. Unfortunately, the mouth became septic and subsequently infected the neck wound. Septic pneumonia supervened, and the patient died on the tenth day after operation. The œsophageal tube was retained to the end and caused little or no inconvenience.

Complete removal of the teeth before operation would probably have lessened the chances of sepsis, and I would certainly adopt this course in any future case. The operation, I think, was justifiable for the relief experienced by the patient at getting rid of a loathsome, painful, ulcerating mass, if for

no other reason. The condition of such patients, even should the operation prove successful, is certainly far from enviable, but, in the absence of power to provide an euthanasia, it is preferable to their pitiful plight if nothing is done.

The absence of hæmorrhage by means of ligature of the external carotids and their branches makes the operation a comparatively easy one. The complete cutting off of the blood-supply, however, favours the supervention of sepsis, and probably a less heroic method of obtaining a dry operation field, such as by a temporary ligature, might be more desirable.

Possibly the retention of the cricoid cartilage was a mistake, as it left the tracheal opening high up in the neck and favoured the entrance of septic discharges. Dr. Dan McKenzie's plan of closing the cut end of the trachea by sutures and leaving the tracheotomy tube *in situ* for some days would undoubtedly have been preferable, and had I had the good fortune to have seen, before operation, the description of his case of laryngectomy in the September number of the *Journal of Laryngology*, I should have adopted it.

Sheffield.

THE REPAIR OF THE FLEXOR TENDONS OF THE HAND: A REVISED TECHNIQUE.

BY C. MAX PAGE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN; DEMONSTRATOR OF ANATOMY, ST. THOMAS'S HOSPITAL.

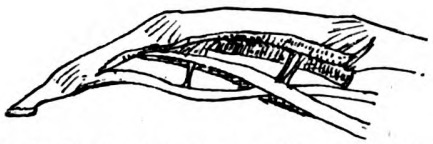
ACCIDENTAL division of one or more of the flexor tendons of the hand is a not uncommon occurrence. Spontaneous healing is rare—in fact, it may be taken as a rule that after complete division surgical interference is necessary if a satisfactory result is to be obtained. In my opinion the average final results of such procedures are not as good as might be wished for. I base this statement on the experience of some 20 cases which have come under my treatment, and on the observations on a much larger number which I have seen in the casualty department of St. Thomas's Hospital. Primary union is by no means the rule. Even if satisfactory healing of the cut surfaces of the tendon results free movement is frequently hindered by adhesions of the scar; and the extensive division of the theca, which is often necessary in order to bring to the surface the proximal divided end, subsequently interferes with the proper transmission of power. After such treatment the tendon springs forward when it comes into action, as its bearing surface is only a layer of fibrous tissue lying just below the skin, instead of being the firm synovial lined theca. The worst results are, I think, seen in the case of the thumb. This is particularly unfortunate for the patient, as a full control of the single flexor tendon of this digit is of the utmost importance in any action of the hand.

The factors which are concerned in the production of unsatisfactory results may be grouped under two general heads—viz., (1) Failure of primary union between the cut ends of the tendon; and (2) incomplete restoration of function in spite of union of the tendon.

1. The failure of union may be due to—(*a*) *Inadequate fixation of the divided ends*—in children especially the frailty of the tendon often renders satisfactory suture by the usual methods very difficult. (*b*) *Infection of the wound*—if any degree of suppuration take place the suturing will almost certainly give way. (*c*) *Too early mobilisation of the injured part*—firm union between the divided ends of tendon in normal cases, according to Betzow,[1] is complete in 60 days, though some post-mortem examinations of Adams[2] prove that fairly firm union is present in about 20 days. Seggel[3] states that complete conversion into tendinous tissue does not take place under 90 days. (*d*) *Undue injury of the theca.* If the latter is extensively laid open to expose the tendon, as may be necessary in cases of late suture, resuture of it will be found impossible. The tendon springs forward, and, instead of being surrounded by synovial sheath, is mainly in contact with the subcutaneous tissues. Such a state of affairs greatly hinders proper repair, for union of the divided ends of a tendon is assisted by the activity of the inner layer of the theca.[4]

2. *Incomplete restoration of function.*—In a certain number of cases, though union of the divided ends has occurred, the action of the tendon is weak or imperfect. Sometimes this is due to the formation of adhesions between the tendon and surrounding structures, and if this is the cause mobilisation under gas and subsequent exercises may effect a cure. If, however, the theca was divided in its long axis to any extent at the operation, the weakness may be a permanent one, due to the forward displacement of the tendon when it comes into action. No doubt irregularities in the surface of the tendon and in the new-formed theca, which at first limit movement, in course of time become smoothed out.

A *résumé* of some of the anatomical points in the region is desirable before describing the technique which I advocate.



The Tendons of the Fingers.

The two flexor tendons of each finger are enclosed in a firm fibrous tissue sheath, the theca, lined by vascular synovial membrane. The theca extends from the head of the metacarpal bones to the base of the terminal phalanx; it is attached marginally to the edges of the phalanges and the lateral part of the glenoid ligaments of the interphalangeal joints. The theca is particularly strong opposite the shaft of each phalanx and thin over the articulations. The sublimis tendon, lying most anterior, divides about the middle of the proximal phalanx, embraces the profundus tendon, and unites again behind it at a level of the proximal joint, and is inserted into the middle of the anterior surface of the middle phalanx. Both tendons are covered by the thin peritenonium, which is continuous with the synovial lining of the theca at the points of insertion of the tendon, and is also connected with it by the delicate vincula accessoria. Of these vincula there are two types, brevia and longa. The arrangement of these vincula is illustrated in the diagram. (Fig. 1.) The two long thin ones have some control of the retraction of the tendons when the latter are divided distal to the vincula. The vinculum longum of the profundus tendon is absent in about 1 case in 10; it passes at the level of the proximal

interphalangeal joint from the ventral surface of the profundus tendon between the split sublimis tendon, being attached to the latter and passing on to the theca. Two paired vincula longa usually pass from the sublimis tendon, just after it has divided, to pass direct to the sides of the theca. In the palm the two flexors for each finger lie superimposed, the sublimis being superficial; they are

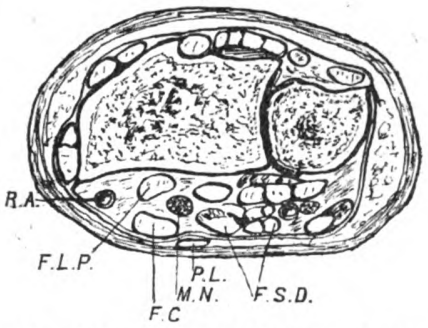

FIG. 1.

Sketch showing typical arrangement of the vincula accessoria to the two flexor tendons.

covered by the palmar fascia. The digital vessels and nerves lie laterally in the spaces between the tendons. The tendons are nearest the surface just proximal to the head of the metacarpal bones, subcutaneous tissue and the thin expansion of the palmar fascia here alone covering them. The superficial palmar arch crosses them at a level corresponding with the middle of the metacarpal bones.

FIG. 2.

The Tendon of the Thumb.

In the thumb the conditions are markedly different. The single flexor tendon is contained in a thecal sheath similar to that seen in the fingers; the tendon is inserted into the anterior surface of the base of the terminal phalanx. It usually has only one vinculum accessorium attached close to its insertion; another long slender one may be present opposite the proximal phalanx. In the thenar eminence the tendon passes in a canal very completely covered by the outer group of thenar muscles. The tendon passes beneath the annular ligament and to its outer side; opposite the wrist-joint the tendon lies in its own thecal sheath just posterior and slightly to the ulnar side of the tendon of the flexor carpi radialis. In this situation it can always be readily found. (Fig. 2.) From the above considerations it will be seen that in the fingers, if the profundus tendon be divided distal to the proximal interphalangeal joint the muscular end will be prevented from retracting any considerable distance by the vinculum accessorium. If division takes place proximal to this level both tendons may retract well into the palm, though the attachment of the lumbrical muscles to the profundus tendons will tend to limit such a movement. In the thumb if the tendon is divided anywhere proximal to its insertion it can retract very freely, since it has at most a slender vinculum to hold it.

General Principles of Treatment.

Taking into consideration the above points, I advocate the following technique with a view to improving the results of operation in this class of case. For the sake of clearness a somewhat dogmatic catalogue of principles may be allowed.

When to operate.—If the wound is an incised one and apparently clean operation should be undertaken within 12 hours of the injury. If the case is seen later the wound should be painted with tincture of iodine and a simple dressing be applied; if on inspection two days later there is no evidence of infection operation may be proceeded with. If the incised wound is suppurating it should be treated on simple lines, the operation being postponed until the skin be soundly healed. In lacerated wounds, seen soon after the injury, whether immediate suture of tendon is undertaken or not, must depend on the degree of injury of the part and the extent to which infective material appears to have been introduced. In any case it will be better to appose the margins of the tear as far as possible and wait till the wound has healed before dealing with the tendons. In cases seen late and when the skin wound has healed completely, operation should be undertaken if there is no sign of union in the tendon two or three weeks after the injury.

Cleansing the wound.—When the wound is an open one any foreign matter should be removed with forceps; the whole surface and the surrounding skin is then freely sponged with tincture of iodine. No preliminary washing with water should be allowed.

Recovery of the cut ends of the tendon.—The distal end can always be readily caught without disturbing the theca, flexion of the terminal phalanx being sufficient to bring it into the wound. In regard to the proximal end, the degree of retraction varies much and is greater in late than in recent cases, but in whatever situation the tendon may lie a rule should be made never to incise the theca beyond the extent of the primary injury. The cut end of the proximal tendon should be sought for with sinus forceps introduced into the theca through the primary opening; the tendon is made to descend as far as possible towards the wound by flexing the wrist-joint and massaging the forearm muscles. If by these means the tendon cannot be caught, it must be picked up through another incision made higher up in the manner described below. To carry out this procedure a flexible bullet probe with an eyehole cut in the bulbous end is required. In the fingers an incision half an inch in length is made directly over the line of the tendon at a level with the neck of the metacarpal bone; after division of skin, subcutaneous tissue, and the thin expansion of the palmar fascia the sublimis tendon (lying close over the profundus) will be found very near the surface. The theca (in this situation, frail and thin) is opened and the divided tendon or tendons are drawn out through the wound; the bulbous end of the probe is then passed from the primary wound through the theca and made to emerge at the secondary opening. A suture is fixed to the cut tendon and threaded through the eye of the probe. The probe is then drawn back and out again at the primary incision bringing the tendon with it.

In the case of the *thumb* a similar procedure is carried out, but the tendon must be picked

up on the proximal side of the wrist-joint. A three-quarter inch incision is made extending upwards from the level of the wrist-joint directly over the ulnar border of the flexor carpi radialis tendon; this tendon is pulled to the radial side, the median nerve is gently displaced ulnarwards, and the tendon of flexor longus pollicis will be seen lying deep and between these two structures (Fig. 2). The tendon will be lying slack, and on this account may appear a little like the median nerve. The theca is incised and the tendon pulled out. Sometimes it may not slip out quite readily; this is usually due to a failure to open the theca, which is thin and not very obvious in this situation. The probe is then passed and the cut tendon drawn back into the primary wound as described above.

Fixation of the cut ends of the tendon.—Any one of the advocated methods for suturing the cut ends may be employed; it should, however, be remembered that adaptation of the cut ends without causing any abnormal deviations is more important than close apposition of the cut surfaces. In some cases, especially in children, it is difficult to get a good hold of the tendon with the suture. In such cases the best plan I think is to hold the cut ends of the tendon successively, at their proper level in the theca; then pass a suture from side to side of the theca piercing the tendon about a quarter of an inch from the point of section; tie the suture with sufficient firmness to hold the tendon in position. Simple iodised catgut should be used for this procedure. Though absolute apposition of the cut surfaces is not obtained by this means, the ends of the tendon lie in their normal relationship and quite close enough for satisfactory healing to take place. I have only tried this procedure once in man, and then with a good result. Some experiments I have recently made on rabbits show excellent early union after suture by this method. No further deep suture should be inserted and the skin wound is closed.

After treatment.—Position. At the completion of the operation I put the digit up flexed on a pad. This position should certainly be adopted if the fixation of the cut ends is of doubtful firmness; it also has the merit of apposing as far as possible the cut edges of the theca, which in practice cannot readily be sewn together. Further, any active movement of the flexor tendon will strain the tendon but little when the finger is in this position.

Mobilisation.—Most authorities agree in concluding that union between the divided ends of tendons under average conditions is in no sense complete until about 60 days from the time of section.[5] After tenotomy of the tendo Achillis it is customary to wait 6 to 12 weeks before permitting full use of the limb. Taking the points into consideration, I think the best results are to be obtained if the finger is left flexed for at least a month after the operation. Massage without movement may be allowed after 10 days, but in young people if the use of the other fingers is encouraged as far as possible the general circulation of the hand will remain good. Complete mobilisation under gas should be carried out about eight weeks after the operation, and up to that time no very vigorous use of the finger should be allowed. If necessary, exercises on a pendulum machine can subsequently be given to complete the restoration of the full function of the parts.

A CASE OF RAT-BITE FEVER TREATED WITH NEOSALVARSAN.

BY N. F. SURVEYOR, M.A., M.D. BOMBAY, M.R.C.P. LOND., D.P.H. CAMB.,

PROFESSOR OF BACTERIOLOGY, GRANT MEDICAL COLLEGE, BOMBAY; HONORARY PHYSICIAN, SIR JAMSETJEE JEEJEEBHOY HOSPITAL.

RAT-BITE fever is a term applied to cases following the bite of a rat. Still, one cannot say that the term connotes an entity, simply because the number of observations on this disease are not many. However, the description of the cases published seems to favour the assumption, yet one must bear in mind the possibility that the infecting organism may be different in some of the cases that one sees.

Recently I have had the opportunity of studying a case of this disease through the courtesy of Dr C. Fernandes, of Bombay, under whose care the patient had come for about three months prior to my seeing her on April 11th, 1913. At this time the patient was suffering from one of the periodic attacks of the fever. She was very anæmic; the face was puffy and pasty in appearance, and on the forehead and cheeks there were reddish wheals; the ears, especially the right one, were red and œdematous; similar wheals were present on the trunk also. The temperature was 103° F., and fever had started about two days prior to my visit.

The history was as follows. The patient, a high-class Hindoo lady, was bitten on the right ear by a rat about eight years ago (in 1906). The wound did not heal, but the ear was considerably swollen and appeared quite black in colour; ultimately it ulcerated, and the ulcer took three months to heal up completely. About a fortnight after the bite the fever commenced, and she used to have a temperature varying between 99° and 105° F., and lasting for from 3 to 7 days. At first there were no eruptions noticed. However, after the ulcer on the ear had healed the fever, which was always ushered in with rigors, was accompanied by large roseolar wheals on different parts of the body, especially the face. The mucous membrane of the mouth and the fauces was also swollen and red, The attacks persisted for all these years in spite of ordinary treatment with quinine, arsenic, iron, and mercury. The patient was left weaker after each attack, and as these came on generally once or twice every month the loss of flesh and anæmia were excessive. When seen first the general appearance of the patient suggested Bright's disease, as the face was puffy and there was some œdema of the extremities. Anæmia was very marked. The roseolar wheals were the most characteristic feature of the fever.

The finger blood, about 1 c.c., was twice examined by cultural tests, but no microbes could be detected. The blood was very watery and almost poured out of the puncture. No malarial parasites could be detected. The leucocyte count was: polymorphonuclears, 89 per cent.; eosinophiles, 0 per cent.; round hyalines, 1 per cent.; and lymphocytes, 10 per cent. Leucocytosis was apparently present. The liver and spleen were not enlarged. The lymphatic glands, chiefly of the neck, were enlarged during the pyrexial periods and disappeared afterwards.

On account of the periodicity of the fever and the peculiar eruption it was thought that perhaps the infecting organism might be allied to spirochætæ, and some of the patient's serum was injected into the scrotum of two rabbits with

a view to obtaining a culture, but with negative results. One rabbit showed a rise of temperature for a couple of days about one week after the injection. The Wassermann test was also applied with rat and guinea-pig heart antigens. The serum was inactivated before testing by Fleming's method, and the complement was supplied by the addition of a known non-syphilitic serum, which was also used as a control test. The result was a negative reaction. However, next day the serum, without inactivation, was tested according to original Fleming's method, and a positive result was obtained with both antigens. These contradictory results seem to show that perhaps the control's serum was rich in complement and the small amount of immune body in the patient's blood had not completely used it up. That the quantity of complement in the serum is not a fixed amount is quite possible, because in some cases of marked syphilitic eruptions the Wassermann test as modified by Fleming has been found negative, and in such cases inactivating the serum and adding the complement from a known non-syphilitic has given a positive result. In such a case it is quite possible that the syphilitic serum must have been very rich in complement. I have actually come across such a case. The urine was found to contain albumin, a few leucocytes, granular casts, and red blood corpuscles. The last were present even during apyrexial periods, but they were much increased with the onset of fever. This seems to show that along with the roseolar state of the skin the kidneys were also similarly affected. There were always marked lumbar pains during the attacks. The menstrual flow had stopped for about two years previously.

As the patient's condition was getting worse it was decided to try an intramuscular injection of neosalvarsan. On April 16th 0·7 grm. of the drug was injected, the temperature being 99°. For about a week the temperature kept varying between 99° and 102°, and there was severe pain at the site of the injection, which was moderately swollen. However, after that the temperature came down to normal and remained so for a fortnight; then it went up to 100° only for a couple of days. There was very little roseolar eruption seen at this time. After another month a little rise occurred, but since then the fever has disappeared, and the patient has been putting on weight and getting stronger daily. The urine still contains traces of albumin, but since Sept. 7th last the red corpuscles have completely disappeared. No casts are now present.

About the time of the injection the patient's weight was 94 lb., and in September it was 118 lb., while on Nov. 11th it was 123 lb. Some two months after the injection the patient was put on metharsinate of sodium by the mouth, as she refused to have injections of any drug, and the improvement in the general condition has been steady.

Since the injection of neosalvarsan in this case I have come across the statement[1] that Hata has collected eight cases of rat-bite fever treated satisfactorily with salvarsan. This seems to favour the belief that the organism is probably a protozoon, as suggested by T. J. Horder in his paper on Rat-bite Fever.[2]

About 12 years ago I had seen a Hindoo lad with the same fever. He, too, had roseolar eruption accompanying the temperature, and salol dissolved in olive oil was found to relieve itching and burning sensation. The temperature used to go up gradually to 105° or 106° F. His blood did not show any organisms at the time, and failed to give any culture. He made a complete recovery under a prolonged course of methylene blue, quinine, arsenic, and mercury, though what part the drugs played in the actual cure could not be ascertained. He has grown enormously stout now, probably due to the prolonged treatment with the drugs mentioned, especially arsenic, as there is no tendency to obesity in the family.

In conclusion, it may be stated that the rash very much resembles that in malarial fevers; however, the examination of the blood settles the point. Again, quinine rash may be easily kept under check by administration of calcium lactate, which was found of no avail in the treatment of the case of the Hindoo lady.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Brachial Arterio-venous Aneurysm treated by Vascular Suture.—Ruptured Intestine.—Endothelioma of the Breast.

A MEETING of this section was held on Dec. 9th, Mr. G. H. MAKINS, the President, being in the chair.

Mr. GILBERT KEMPE read a paper on a case of Brachial Arterio-venous Aneurysm treated by Vascular Suture. It was that of a man, aged 56, who came up for examination of an injured wrist. He had an impacted fracture of the left radius in good position, but by X rays the hand held six large shots. Comment on these showed that they had been received about 25 years ago. The man's wife volunteered that there were so many in the other arm (the right) "that they rattled about like a bird singing." The sound, or sensation, had been noticed for about two years Inspection showed a large pulsating swelling in the arm just below the anterior axillary fold, and in the line of the brachial artery. It was increasing in size, but was not painful. The swelling was soft and compressible, and pulsated regularly. A thrill was easily felt, which was a continuous one, but which had a systolic increase of intensity. The swelling could be traced into the axilla, and a soft pulsating swelling was found beneath the right clavicle. Here a similar thrill could be felt, but it was less marked than in the arm. Pressure on the subclavian artery above the clavicle caused a collapse of both swellings and a cessation of the thrill. Release of the pressure caused the swellings to fill up slowly, but they required several pulsations to become as full as before. Pulsation in any of the superficial veins of the arm, forearm, or thorax could not be detected. The influence of respiration on the swellings was not noted. The right radial pulse was less full than, and in time rather behind, the left. A humming, low-pitched bruit with high-pitched systolic accentuations could be heard over the swelling. The systolic notes were conducted as far as the bend of the elbow. The complete bruit could be heard, but not so loudly, beneath the right clavicle. There was no evidence of intrathoracic aneurysm. The condition presented most of the points necessary for a diagnosis of brachial arterio-venous aneurysm. It was rapidly increasing in size, even while the man was in bed and under observation. It was decided to sever the communication and to restore the ordinary state of the circulation. A dissection showed a communication between the upper part of the brachial artery and the inner of the venæ comites. The communication was not direct, for a small but distinct bulb, of the size of a cranberry, intervened between the vessels. They were therefore dealing, speaking strictly, with a varicose aneurysm. The brachial and axillary arteries above the anastomosis were of the size of a common iliac artery, while below the

artery was of normal size but very tortuous. The median nerve and the other concomitant vein lay on the outer side of the artery. The enormously distended vein lay to the inner side of the anastomosis and was pouched below, forming a kind of cæcum. The ulnar nerve ran across this cæcum, depressing it and closely adherent to it. Dr. Thornton had admirably depicted the condition found. The parts were cleaned and the artery and vein were clamped separately above and below the anastomosis. Special clamps were not available and Durham's hare-lip clamps were utilised. The little varicosity was divided transversely to its axis, and a little towards the venous side. The opening leading from the artery was then closed by (1) a continuous mattress suture, after the method of Dorrance, taking up all the coats of the artery. A round needle and 000 silk were used. This part of the procedure was difficult because the upper arterial clamp did not completely control the vessel, and small systolic spurts were coming through during the suturing. It was not possible that an anastomosing vessel entered between the clamps as the artery was fully cleaned. (2) By an outer row of continuous mattress suture taking up the outer and middle coats. Here the same sized needle and silk were used. The venous orifice was closed by an ordinary continuous suture of 00 catgut. When the clamps were removed both suture lines were found to be blood-tight and the wound was closed. In after-treatment, some morphia was given to relieve anxiety, and to reduce blood pressure, and of course the limb was kept at rest. Mr. Kempe had a note of the man's condition on the day after the operation. His general condition was excellent. His right hand was warm, of good colour, not œdematous, and the right radial pulse was fuller and, in point of time, equal to the left. The subclavicular swelling, thrill, and bruit were absent. His only complaint was of some pricking and tingling pain on the inner side of his hand. They thought this was due to the operative interference with his ulnar nerve. He was allowed up at the end of a fortnight, and then his pulse became rapid, weak, and irregular, and his heart enlarged. He seemed to have some cardiac dilatation. The right pulse became weaker than the left, but at no time was there any sign of embolism, nor did the hand become cold or œdematous. A few days in bed improved the heart condition, and he left the hospital apparently well. He came up to report himself a fortnight later, and said he was quite well but for the tingling pain on the inner side of his hand. His pulse was still rapid (96). The right radial pulse was appreciably weaker than the left. A sphygmomanometer gave a systolic pressure of 120 mm. in the right arm and of 140 mm. in the left. It seemed possible that laminated fibrin had been laid down over the arterial suture, either closing the artery completely or considerably throttling it.

Mr. V. Z. COPE read a paper on the Early Diagnosis and Treatment of Ruptured Intestine, which will be published in full in THE LANCET.

Mr. RAYMOND JOHNSON recounted statistics which he had been able to compile from the records of 12 London hospitals for the years 1908–1912 inclusive. There had been 44 cases of ruptured intestine in all; 35 had died and 9 recovered. After operation 9 had recovered and 21 died, whilst the remaining 14 died without operation. The sites of rupture were as follows: duodenum, 5; jejunum, 22; ileum, 13; small intestine (? site), 1; hepatic colon, 1; rectum, 1. The symptoms which occurred were abdominal pain, with or without tenderness in 21; abdominal rigidity in 16; vomiting in 14; marked shock in 13; increasing pulse-rate in 11; bruising of the abdominal wall in 9; dulness in one or both flanks in 9; diminution or loss of liver dulness in only 4. Irrigation was mentioned as having been performed in only one successful case, but in seven or eight of the unsuccessful cases.

Mr. H. BETHAM ROBINSON described a case of Endothelioma of the Breast which occurred in a single woman, aged 27, who came under his care in November, 1908. In the preceding August she had first noticed a lump in the right breast, which had gradually got larger without any pain or inconvenience. Examination showed two hard nodular masses just above the nipple, one in the outer and the other in the inner quadrant, both fairly well defined yet loosely connected with each other. The skin was quite free except over the outer part, and the gland was not fixed to the deep tissues. There were three hard discrete glands in the right axilla. The condition seemed to be carcinomatous, and the breast was freely removed and the axilla cleared. The growth on section was of a pinkish colour, granular-looking, and did not cup; it was rather sharply defined from the surrounding tissue, which appeared unduly fibrous. Histological examination showed that the most distinctive feature was the appearance of more or less rounded cell masses enclosed in a fibrous connective tissue framework especially dense at the margin to form a sort of capsule. The cells composing the masses were somewhat variable in shape, with deeply staining nuclei and plenty of cell protoplasm. In most of the masses were rounded or oval spaces with a sharply defined margin, and in many of these was to be found a fibrinous coagulum with some entangled leucocytes; round the spaces the cells tended to radiate in columns. None of the clefts were well-formed vessels, and in none of them were red blood discs to be seen. There had been no recurrence in a period of over five years. The tumour was considered to be an endothelioma starting in lymphatics. Attention was drawn to the apparent rarity of this form of breast tumour, but Mr. Robinson considered that many tumours difficult of interpretation, if more critically examined, would probably fall into this group. Its apparent low rate of malignancy was commented upon. Another tumour was referred to, and the specimen shown, which was removed from a lady in December, 1904; this up to date had also not recurred. It was much of the same type as the former, only histological investigation showed that it was a perivascular endothelioma (perithelioma).

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Specimens.—Primary Cancer of Bartholin's Gland.—Pre-eclampsia.—Cæsarean Myomectomy.—Relation of Syphilis to the Uterus.—Fœtus Acardiacus Amorphus.

A MEETING of this section was held on Dec. 4th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

The following specimens were shown:—

Mr. ALBAN DORAN: An Occluded Vagina after Total Hysterectomy.

Mr. J. D. MALCOLM: Sloughing Fibroid with Complete Inversion of the Uterus.

Mr. G. G. ALDERSON: Chrobak's Instrument for Embryotomy.

Mr. WILBERFORCE SMITH: Epidiascope Demonstration of Altmann's Granules in Tissues at Point of Invasion by Squamous Carcinoma of the Uterus.

Mr. S. GORDON LUKER: Hydatidiform Mole and Normal Ovum in Twin Pregnancy.

Dr. HERBERT SPENCER read notes of a case of Primary Carcinoma of Bartholin's gland which he had removed, with the superficial inguinal (carcinomatous) glands, on March 3rd, 1912, the patient being well and free from recurrence on Oct. 21st, 1913. A section through the growth and duct (which was unaffected) showed it to be an adeno-carcinoma with degeneration of the cells, causing it to resemble squamous carcinoma. The disease was very rare, half the cases occurring over 50 years of age. The two sides were affected with equal frequency. The relation of the disease to gonorrhœa and inflammation was discussed and a short clinical history of the disease was given.—Remarks were made by Dr. T. W. EDEN and Dr. H. RUSSELL ANDREWS.—The specimen was referred to the Pathology Committee of the section.

Dr. VICTOR BONNEY reported two cases. In the first, a primigravida, 24 weeks pregnant, was suddenly seized with symptoms of acute pregnancy toxæmia. The urine was diminished and contained albumin and blood. Jaundice and rapid loss of sight occurred. Immediate evacuation of the uterus was effected by performing abdominal Cæsarean section. The toxæmic symptoms disappeared within two days and the patient made a rapid recovery. The second case was that of a primigravida whose uterus was the seat of six large fibroids. Cæsarean section was performed at term and after delivery the tumours were enucleated. The largest was of the size of a melon and was submucous in position. This operation, which he termed Cæsarean myomectomy, should be the operation of choice in all pregnancies complicated by fibroids in which the uterus was uninfected, for pregnancy in a fibroid uterus proved the functional value of the organ.

Moreover, the retractile state of the musculature was peculiarly favourable for enucleation.—Remarks were made by Dr. H. WILLIAMSON, Dr. AMAND ROUTH, Dr. G. BLACKER, the PRESIDENT, Dr. R. D. MAXWELL, and Dr. EDEN.

Mr. H. BECKWITH WHITEHOUSE (Birmingham) in a paper on the Relation of Syphilis to the Uterus pointed out that the occurrence in the uterus of lesions the result of syphilitic infection had long been regarded as extremely rare, and very little had been written upon the subject. If it was true that the corpus uteri possessed a definite immunity to the ravages of the spirochæta pallida it was of considerable interest, especially as the relationship was so intimate in connexion with placental and fœtal syphilis. But he considered rather that syphilitic lesions of the uterus had been overlooked in the past. In 1912 he had suggested that the underlying pathological factor in some cases of chronic metritis and fibrosis uteri might be syphilis. He had since investigated by the Wassermann reaction 16 patients with a clinical diagnosis of this nature, seven of whom showed a well-marked positive reaction, although only one gave other evidence of direct syphilitic infection. In three it was necessary to remove the uterus on account of severe hæmorrhage. The uteri from these cases all showed well-marked fibrosis and perior endarteritis of the vessels. The pathological picture coincided with the appearances seen in interstitial myocarditis, orchitis, hepatic cirrhosis and other indurative conditions generally considered due to syphilis. Why, in the case of the uterus, therefore, was it necessary to call for other factors such as septic inflammation, repeated pregnancy, &c., to account for an exactly similar lesion, especially when the Wassermann test showed that a certain proportion of such patients were undoubtedly infected. He pointed out that some cases of pyometra unassociated with malignant disease appeared to bear a distinct relation to syphilis. Specimens from five cases of menstrual blood collected through an intra-uterine catheter during the secondary stage of syphilis showed in two cases the intracellular bodies described by McDonagh and Ross. The presence of such bodies in the menstrual discharge proved a possible source of infection to the uterine tissues through which they passed. The spirochæta pallida had not yet been demonstrated in the menstrual blood.—Remarks were made by the PRESIDENT, Dr. ROUTH, and Dr. BLACKER.

Dr. M. J. STEWART (Leeds) introduced a case of Fœtus Acardiacus Amorphus. He gave an account of a typical example of the fœtus acardiacus amorphus (with drawings and radiographs). The specimen consisted of a trunk-like mass without head or limbs, to the flattened ventral aspect of which the umbilical cord was attached. Radiographic examination showed a vertebral column of 18 segments, to the upper seven of which ribs were attached. Posteriorly the pelvis was represented by two bones on each side, but of limb bones there was not the slightest trace. Dissection and microscopic examination showed the presence of liver and bowel, kidneys, ureters, and testes, but heart, lungs, spleen, and adrenals were all absent.—The paper was discussed by the PRESIDENT and Dr. BLACKER.

SECTION OF LARYNGOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Dec. 5th, Dr. D. R. PATERSON, the President, being in the chair. The following exhibits were shown:—

The PRESIDENT: Three foreign bodies, the colour of which made extraction more difficult. (1) Red Seed from Bronchus, (2) Pink Coral Ring, and (3) portion of red vulcanite Toothplate from the gullet.

Dr. G. WILLIAM HILL: 1. Epidiascope exhibition of Skiagrams and Diagrams of Pharyngeal Diverticula, including X ray prints of four cases examined by the exhibitor. 2. A patient from whom a Post-cricoidal Pharyngeal Diverticulum was recently removed by operation.—The PRESIDENT remarked on the difficulty usually experienced in finding the opening of the œsophagus.—Mr. E. B. WAGGETT related cases in which the patients were taught to syringe out their pouches after dinner regularly.—Mr. E. D. DAVIS related the satisfactory post-operative history of 8 cases out of 11 which he had traced, which were chiefly cases operated upon by Butlin.—Mr. HERBERT TILLEY, Mr. T. B. LAYTON, Mr. H. W. FITZGERALD POWELL, Mr. NORMAN PATTERSON, and Dr. J. DUNDAS GRANT also took part in the discussion.

Mr. TILLEY, Mr. SOMERVILLE HASTINGS, and Mr. A. J. MARTINEAU each showed results of cases of Sarcoma of Nasopharynx treated by radium or radium emanations.—The cases were discussed by the PRESIDENT, Dr. P. WATSON-WILLIAMS, Mr. WAGGETT, Mr. C. W. M. HOPE, and Dr. W. JOBSON HORNE, the latter emphasising the necessity of establishing the malignant nature of these growths beyond any doubt before publishing the cases as cured.—Mr. FITZGERALD POWELL and Dr. HILL also took part in the discussion, and Mr. W. D. HARMER stated that recurrence would take place for certain at a later date.—Mr. MARTINEAU and Mr. HASTINGS replied, and Mr. TILLEY remarked that the closer the resemblance of these growths to embryonic tissue the greater the likelihood of benefit to the patient by this form of treatment.

Mr. LAYTON: Two cases of Bilateral Abductor Paralysis.

Mr. A. J. M. WRIGHT: Specimen of a Thyroglossal Cyst causing dyspnœa in a woman aged 54.

Mr. G. POTTS: Laryngeal case for diagnosis in a man, aged 45, who had hoarseness for five years, a swelling over the right side of thyroid cartilage for one year, and a laryngeal swelling which obscured the rima glottidis. Sterile pus had been withdrawn by exploratory puncture.—Dr. DUNDAS GRANT and Mr. HAROLD BARWELL suggested that it was a case of tuberculous perichondritis.

Dr. J. DONELAN: 1. Vertical and horizontal gripping forceps for use in various tonsil operations. 2. A combined septal resector, comprising knife, with straight and curved instruments for raising the muco-perichondrium.

Mr. E. A. PETERS: 1. Case of Polycythæmia rubra. 2. Infiltration of both vocal cords; deflected septum.—Dr. JOBSON HORNE and the PRESIDENT thought that benefit would occur when the nasal obstruction was removed.—Sir STCLAIR THOMSON suggested that it might be a case of early tuberculous laryngitis.

Mr. H. D. GILLIES: Case of swelling on the left vocal cord for diagnosis in a man, aged 50, who became suddenly hoarse in March, 1913, after singing.—Dr. JOBSON HORNE thought the swelling was benign.—Sir FELIX SEMON related a similar case which was observed for 18 months, and then was proved by operation to be malignant.—Mr. W. HARRISON also discussed the case.

Mr. NORMAN PATTERSON: Epithelioma of Soft Palate, which had undergone three operations and was now undergoing X ray treatment. (Specimen and microscopical section were shown.)

Mr. THOMAS GUTHRIE: Tooth-plates and meat-bones removed from the œsophagus, together with radiograms by Mr. C. Thurstan Holland.

Mr. G. H. L. WHALE: Trauma from adenoid operation in a child who now showed a trellis-work of adhesions between the Eustachian tube and pharyngeal roof.—Mr. PETERS thought the result was probably due to injury from the finger nail operation.—Dr. JOBSON HORNE and Sir STCLAIR THOMSON thought that the adhesions were not due to faulty technique.—Mr. NORMAN PATTERSON related several similar cases.—Dr. DUNDAS GRANT suggested that faulty involution was the cause.

Dr. W. H. JEWELL: Aphonia in a boy, aged 14, with chronic rhinitis.

Dr. F. W. BENNETT: A case of Ulceration of the Fauces.—Sir STCLAIR THOMSON suggested pemphigus or tuberculosis.—Mr. TILLEY thought it was tuberculosis because of the suggestive appearance of the larynx.

Mr. TILLEY: Swelling of the Palate, which extended to the parotid region of the same side (left).—Mr. LAYTON thought the swelling to be cystic.—Mr. TILLEY said he intended treating this case with radium.

Mr. CECIL I. GRAHAM: Carcinoma of Party Wall, after laryngectomy in 1910, shown before the section in 1911, with recurrence in the scar three and a half years after the primary operation.

Dr. ANDREW WYLIE: A case of Chronic Laryngitis in an unusual form.

Mr. BARWELL: 1. Nasal Obstruction from a polypoid mass in a girl aged 15. 2. Fungating Mass in Right Tonsil in a boy aged 16. A microscopical section would be made to determine the diagnosis of this case, which presented unusual features.

Mr. PATRICK DEMPSEY: Specimen of Œsophageal Diverticulum removed by operation three years ago.

Mr. LAYTON: Subglottic Swelling in a man aged 40.

SECTION OF ANÆSTHETICS.

Fatalities Occurring during Anæsthesia.

A MEETING of this section was held on Dec. 5th, Dr. J. BLUMFELD, the President, being in the chair.

Mr. A. L. FLEMMING read a paper on Fatalities occurring during Anæsthesia, as reported in the lay press from 1910–1913. He regretted that the results and figures could not be of great scientific value, as so many of the reports were very meagre in detail, and proceeded to point out that the present system of inquiry into these matters by coroner and jury was useless both from a medical and legal point of view. Most of the fatalities had occurred, so far as he could discover, when the anæsthetic was being given by men who had no special experience in the administration, and he urged the teachers to remember that very often the student learnt from observation, and that when he saw experts giving chloroform with ease and without accidents occurring he was apt to think the administration easier and safer than it really was. He (Mr. Flemming), therefore, urged teachers to impress on the student that ether was the anæsthetic for the inexperienced and that chloroform should be left to the skilled and expert man. He said that a large proportion of the fatalities appeared to have been due to the selection of the wrong anæsthetic for the particular case, and gave as an instance the administration of nitrous oxide to a patient suffering from angina Ludovici. He further pointed out that a considerable number of deaths had occurred before the operation had started, and in almost all of these cases the anæsthetic used for induction was chloroform and the patients had died in the struggling stage. This, he maintained, showed clearly that it was better and safer to induce anæsthesia either with gas and ether or ether rather than with chloroform.

Sir FREDERIC HEWITT said that he took a keen interest in Mr. Flemming's paper because it clearly demonstrated the pressing need of certain reforms in regard to deaths connected with anæsthetics. It was simply appalling that so little notice was taken of the unnecessary wastage of human life, which so often occurred. Whilst it could not be denied that many of these fatalities were unavoidable, he (the speaker) had no doubt in his own mind that in a large number of the cases, possibly in the great majority, life might easily have been saved had the proper anæsthetic been used and the administration been conducted by an experienced administrator. Mr. Flemming's statistics lent great weight to the contention lately put forward by Dr. W. A. Brend that the coroner's court, as at present constituted, was not only useless but harmful when it essayed to inquire into deaths connected with anæsthetics. It was little short of a farce for coroners' juries to express views as to how and why patients died during surgical anæsthesia. It was the duty of the medical profession to combine and to urge the introduction of some kind of private inquiry as a substitute for the present coroner's inquest. Such an inquiry should be conducted by a trained medical man, with or without an expert assessor. The present system was useless because the information asked for and obtained was not useful for scientific and statistical purposes; it was harmful because it inflicted unnecessary pain and discredit upon the relatives of the deceased and the medical practitioner One of the recommendations of the Home Office departmental committee, appointed a few years ago to consider, *inter alia*, the administration of anæsthetics, was to the effect that "a small standing scientific committee on anæsthetics should be instituted under the authority of the Home Office," but this recommendation, like others, has become a dead letter. Such a committee would be most valuable as an intermediary between the private Home Office inquiries on the one hand and the various professional and educational bodies on the other. Amongst the latter bodies he might mention the Section of Anæsthetics he was now addressing, the General Medical Council, and the British Association for the Advancement of Science. He (Sir Frederic Hewitt) was aware that the Royal Society of Medicine, being essentially a scientific body, was disinclined, if not unable, to take any part in the reforms that were needed. But surely the matter was of such moment that the Section of Anæsthetics might, as a scientific body, further the introduction of reforms, and work in conjunction with other bodies to remedy the existing defects in medical practice. The two other bodies to which he had referred, viz., the General Medical Council and the British Association for the Advancement of Science, already had anæsthetics committees. The committee of the General Medical Council, however, as at present constituted, existed only for the purpose of considering any proposals that might be made for legislation. Possibly it might be found practicable for the functions of this committee to be extended so that it might from time to time advise the Council as to what regulations should be issued to the profession in regard to the selection and use of anæsthetics. Similarly, the Anæsthetics Committee of the British Association would also issue reports and recommendations. In this way the Home Office Committee would, on the one hand, be in touch with the General Medical Council, the British Association, and the Royal Society of Medicine; whilst it would, on the other hand, receive the reports and statistics furnished by the private inquiries conducted by its officers upon deaths during anæsthesia. The machinery thus established would be of the utmost importance to the community. There could be no doubt that had ether been used in the great majority of the cases in the opening paper, or had chloroform been administered by the percentage system, many lives would have been saved. Surely there should be some such machinery as that suggested for the guidance of the profession, machinery by which the General Medical Council would issue regulations for the safety of patients during anæsthesia, and by which the Home Office Anæsthetics Committee could obtain reliable statistics as to the frequency of deaths under anæsthetics and other particulars.

Dr. LLEWELYN POWELL dealt with the difficulty of making the student realise the importance of keeping the air-way clear, and thought that probably men preferred to give chloroform as it was easier to give on a mask than to give ether with some of the complicated apparatus in present use.

Dr. A. GOODMAN LEVY touched on the question of auricular fibrillation, and went on to suggest that the section might be able to take up the collecting of reports of anæsthetic fatalities so that a proper record could be made.

Mr. H. E. G. BOYLE commented on the relatively large number of deaths reported under N_2O, and thought that under more ordinary circumstances and with usual care death ought never to occur under N_2O. He alluded to the fact that most of the fatalities had occurred with men who had had a very limited experience of anæsthetics, and felt that it was high time that the public at large realised that they ran a decided risk in allowing themelves to be anæsthetised by inexperienced men. He dealt with the large number of cases that had died before the operation had begun, and in whom $CHCl_3$ had been used to induce anæsthesia. For a long time he had held that it was dangerous to induce with $CHCl_3$, and felt that if anæsthesia was induced with gas and ether, and then continued either with ether or chloroform, the death-rate would sensibly diminish. He felt that cases ought always to be reported, but the coroner and jury system was wrong. Either a board of medical men or anæsthetists to act as advisers to the coroner should be appointed.

SECTION OF PSYCHIATRY.

Exhibition of Cases.

A MEETING of this section was held at the Bethlem Royal Hospital, St. George's Fields, on Dec. 9th, Sir GEORGE H. SAVAGE, the President, being in the chair.

Dr. W. H. B. STODDART, the medical superintendent, showed an interesting series of cases. The first was a middle-aged woman suffering from loss of memory and some paramnesia and peripheral neuritis. It was polyneuritic psychosis, with very severe peripheral nerve disturbance. She had both rectal and vesical difficulty, though probably of mental causation. She was constantly hearing voices. The next case was one of Apraxia in a woman, aged 54, who four months ago had a slight attack of hemiplegia, followed by mild aphasia. She now had ideational inertia on the agnostic side; she would name articles first shown her correctly, but later she could not do so. There was probably either a senile cortical atrophy, or a disturbance and disorder of cerebral vessels. He also exhibited a case of Hypopituitarism in a married woman, aged 69, who was admitted ten months ago with mental confusion and occasional lapses of memory, restlessness, hallucinations of vision, and

cutaneous sensations, which latter had now passed off. The patient had recently developed thickening of lips and tongue. She had an increased capacity for sugar, being able to take 350 grm. of dextrose without any being excreted. She improved while taking large doses of pituitary extract, but not upon thyroid extract. She was mildly depressed but sometimes witty. Other cases shown were a girl, aged 18, the subject of Anxiety Neurosis, who had shown moral lapses in the direction of lying and stealing, and later became uncontrollable; a married woman, aged 45, the subject of Dementia Paranoides; and a similar one in a single woman, aged 47, who considered a Paris hypnotist responsible for casting a spell over her.

Dr. RALPH BROWN showed a case of Congenital Neurasthenia in a man aged 19. No nervous heredity, but when 9 years of age he received a blow on the head. In 1912 he became morbidly introspective, and felt he had committed the "unpardonable sin" (blasphemy). He recently threatened suicide.

Dr. BROWN also showed an unusual case of General Paralysis in a man. He had a brother an epileptic. There were visual and auditory hallucinations, and memory, both recent and remote, was poor. Knee-jerks increased, but no other physical signs of general paralysis. Lumbar puncture in May showed the cerebro-spinal fluid normal. Wassermann reaction (both blood and cerebro-spinal fluid) negative. Speech slow and rather hesitating, with some fibrillary tremor of the tongue. He had delusions of a megalo-melancholic nature, and auditory hallucinations of a persecutory type. There had been no anti-syphilitic treatment. It was not uncommon for cases of general paralysis to reach an advanced stage with but little abnormality of pupils; but it was less common to find the Wassermann test negative. The last patient was a man, aged 23. Six weeks ago he was admitted to the Bethlem Royal Hospital in a maniacal condition. The excitement was now diminishing, but the patient was still very exalted and had expansive and grotesque delusions, with auditory and visual hallucinations. Memory good and no confusion. General health was fair. The case was regarded as one of acute mania, general paralysis, or dementia præcox of the paranoid type, probably the last.

HUNTERIAN SOCIETY.

Migraine.

A MEETING of this society was held on Nov. 26th, Dr. W. J. M. ETTLES, the President, being in the chair.

Dr. A. S. CURRIE opened a discussion on Migraine. He said that nothing worse in the way of poignant suffering could well be imagined than the intense headache, photophobia, hemianopia, scintillating scotoma, and other concomitants of the disease. Hughlings Jackson truly described migraine as the congener of epilepsy, and, accepting this view, Dr. Currie would classify these maladies in the following order: (1) migraine; (2) minor epilepsy; (3) gross epilepsy. Sir William Gowers had seen migraine cease on the appearance of epileptic convulsions, to reappear on the cessation of the convulsions. Migraine was more closely allied in its phenomena to minor than to major epilepsy. There was a striking similarity between the first two in the dreamy states, and diplopic mentation often observed in both and in the after-languor which was also present in the major state. Dr. Currie gave a series of cases from his note-books illustrating the various types of migraine, most of which exhibited the phenomenon of "reminiscence." He also gave family histories of cases of migraine where one or more members of the families suffered from true epilepsy. While he had had a large number of cases in women, he had also had a large number among professional men, and generally the cases were met with among those of a high standard of intellectuality. Another feature in a few of his cases was that instead of "reminiscence" there was a sense of gigantism during the attacks. Reference was made to the exciting causes—e.g., ocular defects, gout, rheumatism, and defective metabolism. For the relief of pain during an attack phenacetin in 15 to 20-grain doses at frequent intervals was found to give greater relief than any other drug. "Reminiscence" was a symptom of the condition rarely mentioned in text-books or even in monographs on the subject, and yet it was a frequent concomitant of the disease. From the biography of Charles Dickens it appears that he suffered from "dreamy states," and the description in the character of David Copperfield of his having been on a previous occasion in precisely the same circumstances and environment was doubtless a personal experience of the author's. The phenomenon of "reminiscence" was best described as a "mental diplopia." Dr. Jackson wrote[1] that there was a close analogy between the visual diplopia of ophthalmologists and mental diplopia. In the former with *slight* divergence of the visual axes there was *more* visual confusion; in the latter with a *shallow* dissolution of the highest centres there was *more* mental confusion. Dr. Currie suggested that in migrainous reminiscence there was a gradual development from a faint mental picture to a clear-cut, definite impression, and that the latter evoked the memory of the former and appeared as a mental diplopia. He had noticed a similar phenomenon in regard to auditory impressions. Migrainous patients had been observed to sit for some time silent after being questioned, and then without the question having been repeated to awake to the fact that they had been questioned, and return a correct answer. In migrainous mental diplopia the dissolution of the highest centres was more shallow than in minor epilepsy, and this constituted a sharp dividing line between the two maladies.

Mr. SYDNEY STEPHENSON urged the dependence of many cases of migraine upon eyestrain. He considered that the refraction should be corrected as a routine measure in every case of migraine, and he did not think that a practitioner could be said to have consulted the best interests of his patient unless he had taken that step. It was very important to understand that relief might often be given by suitable glasses, all the more so since the condition could not be said to be definitely or consistently under the influence of any medicament, ancient or modern.

Mr. C. WRAY said he hesitated to assume that he had cured *true* migraine by glasses, but in over 35 per cent. great benefit resulted, and the attacks were lessened in number, duration, and severity, even without the use of drug treatment. Too much was expected from weak cylinders and far too little from reading glasses to correct weak accommodation, which was not unfrequently present. At times young migrainous subjects with lowest grade astigmatism required in addition to the cylinder correction + 0·75 to + 1·25 spherical for reading and close work—a sufficient proof that the accommodation should receive as much attention as the examination of the distant vision. In such cases, if the patients were poor, it would seem best to try the spheres only for close work and ignore the expensive cylinders, having recourse to them only when the simpler glasses failed. The spectacle treatment of migraine should be largely determined by the frequency of the attacks, and it was particularly desirable not to disfigure young females and some men with constant use of glasses when the attacks occurred at long intervals. It was doubtful if exact correction with 0·25 cylinders could be made by subjective tests. Even a small error in the axis of a cylinder caused a somewhat glaring distortion of plane geometric figures. The patient's complaints were too vague to put the average practitioner on the right track, but this so-called metamorphopsia was easily detected by directing the patient to notice the sides of the Jaeger type mount. A side seen through a wrongly placed cylinder would be at fault, and if the axes for both eyes were wrong and the patient had binocular vision both the right and left sides would be at fault, and the mount would seem too large at the top or the bottom. At times this was due to cyclophoria, in which instance the distance cylinder could not be tolerated for reading. Occasionally patients were assured the discomfort from the glasses would soon disappear, and this was true, as the more intelligent ones suppressed the image seen by the more troublesome eye. This mostly implied the development of exophoria and the addition of aching at the back of the eyes to his sufferings. Migraine was due to a number of causes acting at the same time, and a careful examination of the nose should be made for spurs and enlarged turbinates impinging on the septum. At times when an attack subsided rapidly the patient had a sensation as of an obstruction giving way, and this was no doubt due to the shrinking of the vascular tissues of the middle turbinate. At the patient's first visit the frequency, duration, and severity of the attacks should be ascertained, also the prodromata and their duration, the behaviour of the

[1] THE LANCET, vol. ii., 1887, p. 890.

stomach during the attack, and the commonest exciting causes. Patients in whom the theatre or similar entertainments caused an attack should take 15 grains of bromide of potassium, one dose before leaving home and a previous one three hours earlier. The drug might be similarly used in cases in which a railway journey precipitated an attack. At times migrainous patients who vomited several hours after drinking beer had an odour of it in the vomit. In such cases the administration of drugs by the mouth was likely to be a failure and illustrated the importance of allowing at least three or four hours to elapse after a meal before having resort to their use. When the patient awoke with premonitions the greatest success was obtained from phenacetin and caffeine. There were many objections to prescribing tablets, but the rarer the attacks the more necessary they became, as it was impossible to keep liquid preparations for an indefinite period. The first step should be to ascertain the tolerance of the patient to the drug. The number ordered should be put into a wineglassful of water and crushed, after which a teaspoonful of spirit should be added. When the patient awoke with distinct premonitions he should take his tablets, go back to bed, and not take any food for at least an hour. The success of this method was very considerable and the efficiency of the drug greatly increased by the addition of the spirit.

Mr. REGINALD EVERSHED was of opinion that migraine was due to an error of refraction plus some form of toxæmia caused by a defective metabolism of certain purins, and that if migraine was not a form of youthful gout, as suggested by Trousseau, there was a close connexion between them. Personally, he was inclined to follow Trousseau's lead, both from an individual acquaintance with the malady for 30 years and from experience gained in general and special practice for 24 years. The following reasons led him to this conclusion: in patients subject to migraine a history of gout could usually be obtained, and in later life when the migrainous attacks had passed away gout in some other form made its appearance; further, the predisposing factors in an attack of migraine, other than the error of refraction, were similar to those which precipitated an attack of gout. Treatment to be curative must be continuous, and for the past five years Mr. Evershed said he had adopted the following method with success: the first essential was to fully correct the error of refraction and to re-examine the refraction periodically, then the patient was instructed to take every night 5 grains of acetosalicylic acid, and once a week a purge containing mercury in some form, and on the following morning a mineral water; the doses of purge and mineral water should be so adjusted that one thorough evacuation was caused. The patient should also avoid certain articles of diet, such as soups, sauces, and gravies made from bone stock, high game, sweetbreads, liver, and kidneys, jellies, and abstain from beers and whiskies; finally, the clothing worn should be regulated relatively to the temperature of the air. Should it be necessary to prescribe treatment for an attack the following would be found to give relief: abstention from food, or if it was necessary to take some, then hot water arrowroot only, rest in bed, the patient wearing a warm night-cap, and having a hot-water bottle in bed, and an extra covering on the bed; in these cases where it was impossible for rest to be taken, then 10 grains of phenacetin, followed in an hour by 5 grains, would give relief, especially if half an hour could be spent in front of a hot fire; but this palliative treatment would only postpone the attack, and it was probable the next one might be more severe than usual. Whatever the treatment adopted, Mr. Evershed wished to emphasise the fact that it was absolutely indispensable to obtain an accurate and full correction of the error of refraction, even to the extent of using atropine in an adult patient, and that the glasses to correct the error must be worn constantly.

Mr. ARTHUR COOKE said that the last three speakers had taken up a strong view that migraine was chiefly caused by eyestrain, in contradistinction to the Vice-President, who seemed to incline to the view that it was closely allied to "petit mal." Much depended in this connexion on whether a large number of ocular headaches closely resembling migraine were to be included in the same category, and a distinction was required. The following definition of migraine would probably be agreed upon: "A paroxysmal affection characterised by severe headache, generally ushered in by some premonitory symptoms, often associated with nausea and vomiting." The premonitory symptoms were usually visual in the form of scintillating scotoma, but might take less noticeable forms; and in a few cases, which must be classed as migraine, might be absent. Such attacks would not include the common ocular headache, and he ventured to suggest that the last speaker, in finding 12 per cent. of migraine cases in his refraction cases, had included some types of headache which were not usually considered to be migraine. Such curious explanations had been given of the pathology of migraine as the following: "a limited arterio-sclerosis," "uncontrolled action of the sympathetic system ending in its exhaustion," and by Dr. Spitzer in 1901 it was stated to be due to "stenosis of the foramen of Winslow." Probably the simple explanation was that migraine was due to two factors—first, the irritable or explosive condition of the central nervous system; and second, some irritation from the periphery, usually eyestrain. When migraine took place there was an explosive outburst, apparently out of all proportion to the cause. The proof that eyestrain was the actual cause was given mainly by the treatment—that is to say, correction of the eyestrain by suitable lenses relieved or abolished migraine in a vast proportion of cases. Just as the diagnosis of tertiary syphilis was proved by the treatment by iodide of potassium and consequent abolition of the lesion, so the origin of migraine in eyestrain was proved by the relief of the condition when the eyestrain was removed. As to that relief, a brief abstract of cases would show this. In refraction cases extending over five years, about 3,500 cases yielded 28 cases of migraine. Nineteen had been cured or much relieved, in one no change took place, three were better from other causes not connected with the eyes, and five had been lost sight of.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Treatment of Abortion.

A MEETING of this society was held on Nov. 26th, Dr. LINDSAY, the President, being in the chair.

Dr. J. NIGEL STARK showed a specimen of a Cervical Fibroid with a small Intrauterine Polypus which had been the cause of severe hæmorrhage.

Professor R. JARDINE showed a Uterus removed for adenocarcinoma.

The PRESIDENT showed a series of specimens illustrating Necrobiosis in the Embryo.

A discussion on the Treatment of Abortion was introduced by Dr. JAMES TODD, who spoke from the point of view of the general practitioner. Dr. Todd said that sometimes the term abortion was limited to those cases where pregnancy terminated during the first three or four months, but he proposed to speak of it as the termination of pregnancy before the child was viable. The importance of the subject was recognised by medical men, but the public still regarded it as a less serious condition. A large proportion of cases received no medical attention. Dr. Todd's experience was that only 10 or 12 cases out of 30 to 50 abortions were treated by medical men. Practitioners should do all in their power to educate the public in the dangers incident to abortion. Preventive treatment depended on a knowledge of the antenatal pathology. Anæmia, malaria, and syphilis were mentioned as well-known causes. The exciting cause frequently was over-exertion or some local lesion—e.g., displacement of the uterus, myomata, or most commonly endometritis. In cases usually termed "habitual abortion" iron with chlorate of potash was useful in treatment. In threatened or recurring abortion treatment depended on diagnosis, and this was sometimes difficult. Extrauterine pregnancy had to be kept in mind. If pregnancy was diagnosed the question whether the abortion was avoidable or inevitable was a vital one. When hæmorrhage was the leading symptom its continuance alone should not be taken as proof of inevitable abortion. If the bleeding was sudden and large it generally denoted separation of the ovum. Rest in bed and rest to the reflexes by opium were recommended if the pregnancy was likely to resume its normal course. In many cases of inevitable abortion Dr. Todd had felt justified in adopting an expectant attitude. The patients feared an operation and grudged the expense, and the conditions of the house were not without danger. Two conditions of the patient which compelled interference were excessive bleeding and signs of sepsis. Plugging the vagina in a working-class house was

difficult and dangerous, and of little use in preventing bleeding. Evidence of early septic infection meant emptying the uterus. Frequently the uterus could be cleared out thoroughly with the finger, if not by the gentle use of a blunt curette. The good result of emptying the uterus was frequently very striking. Dr. Todd considered that routine douching after operation might very easily do harm. He usually kept the patient in bed a shorter time than after a normal labour.

Professor JARDINE discussed the subject from the consultant's point of view. He remarked on the increase of cases of abortion which had been noted in the practice of the Glasgow Maternity and Women's Hospital recently. The consultant's point of view was essentially that of the practitioner—viz., the best treatment for the patient. He had not yet found a case where he could say it had been properly plugged before coming to hospital. A few tampons of wool in the vagina were not a sufficient plug and did not do any good in preventing bleeding. He had found that chlorate of potash was a useful drug and had good effects from it in many cases. In using the curette he advocated an instrument with a large loop, but with a sharp edge, as it was not easy to remove adherent decidual tissue otherwise. Professor Jardine thought that sometimes a misconception arose in practitioners' minds as to when an abortion was complete, and he had found in examining students that no clear idea was given by most of them as to what was included in the term "ovum." It was important that this point should be emphasised to practitioners who undertook the treatment of these cases of abortion. In septic cases often those with profuse discharge got well, while those with little or no discharge were really cases of septicæmia and were very fatal. Professor Jardine pointed out the dangers of bleeding and urged efficient plugging, which required really a large quantity of sterile gauze if the plug was to be of any use.

Dr. STARK asked regarding syphilis as a cause of abortion. He remarked on the increase of cases seen at the Royal Samaritan Hospital. He preferred the use of the curette rather than the fingers. He thought the vaginal plug of little use in the treatment of bleeding, and advocated ergot.

Dr. CASKIE urged the use of a large plug and the administration of ergot and opium.

Dr. E. H. T. OLIPHANT mentioned the use of large doses of chlorate of potash up to 40 grains, and had seen it used for months with beneficial results. He referred to its action on the bowel. He suggested the investigation of a large number of cases for data as to the causes of abortion, and referred to the medico-legal aspect of the subject.

Dr. CRAIG thought that the increase in cases seen at the special hospitals was due to the fact that the general hospitals were refusing these cases. He used a large plug, and was not satisfied that the plugging was sufficient until pressure on the bladder was complained of. He spoke of syphilis and intestinal toxins as causes of abortion.

Dr. MACFARLANE advocated the value of plugging in abortion cases.

Dr. CAMPBELL remarked on the growing use of abortifacient drugs, and mentioned a case where a bone needle had been used to procure abortion, and the needle had become impacted in the vagina.

The PRESIDENT said that some cases of abortion were inevitable from the time of conception, and the causes were to be sought between ovulation and impregnation, and also during the early period following conception. He mentioned the influence of vaginal bacteria, and referred briefly to this cause of abortion in cattle. He advocated as treatment rest, opium, and ergot properly administered. He thought that ergot hindered complete expulsion if given when the ovum was being expelled. He described the use of plugs as stimulating the vaginal reflex, especially if the plug pressed on the vaginal fornices.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.

A MEETING of this section was held on Nov. 7th, Dr. M. J. GIBSON, the President, being in the chair.

The PRESIDENT exhibited a specimen of Fibroid Uterus removed after Cæsarean Section for Obstructed Labour and Placenta Prævia, from a woman aged 36, admitted to hospital in a collapsed condition, the vagina having been packed first by a clinical clerk, with a history of having had hæmorrhage for several hours previously. The patient made a good recovery. The specimen raised important questions: firstly, the value of Cæsarean section for the immediate control of hæmorrhage in placenta prævia; secondly, the treatment of a single large interstitial myoma after Cæsarean section; and thirdly, the value of hysterectomy in cases which were probably septic.

The PRESIDENT also exhibited a specimen of Cancer of the Ovary removed from a patient, aged 63, who had never borne a child. She had suffered very little pain. The tumour was removed entire, together with the uterus and the other ovary *en masse*. The patient made a good recovery. The points raised were the necessity for removing all the cysts of the ovary entire and the need for removal of the other ovary and uterus in cases of cancer.

The PRESIDENT also showed sections from another case in which the ovaries and uterus had become cancerous in a patient whose breast had previously been removed for cancer.

Dr. B. A. H. SOLOMONS, Dr. GIBBON FITZGIBBON, and Dr. H. JELLETT took part in the discussion, and the PRESIDENT replied.

Dr. JELLETT showed a Submucous Myoma removed by Myomectomy from a woman aged 30, admitted on Oct. 18th, 1913. She had been married three months, and had not been pregnant. She complained of a tumour, which she first noticed a year and a half previously. It was then about the size of an orange, and had been growing steadily ever since. The abdomen was found to be occupied by a tumour reaching up to the umbilicus, hard, and incorporated with the uterus. A submucous myoma, the size of a large orange, was found projecting from the cervix, and probably continuous with the tumour above. Around this the cervix could be felt very much thinned out and dilated.

Dr. JELLETT reported a case of Full-time Extra-uterine Pregnancy with Uterus in a patient admitted on June 12th, 1913, aged 38, married 15 years. She had four children at term, four abortions, and was pregnant at term when admitted. On admission the top of the fundus was just above the umbilicus No fœtal heart heard. Two days later—that is, June 14th—an attempt was made to induce labour by Krause's method. The cervix seemed somewhat hard and small for a pregnant cervix, but nothing else abnormal. Bimanual examination afforded no information. Two bougies and tents also were inserted, and the vagina was packed with iodoform gauze in sterile glycerine. On the following morning, as labour had not come on, the tents and bougies were removed, more tents inserted, and the vagina packed as before. Next morning, still no labour pains, so the tents were removed. Fœtal head felt low in posterior fornix. A foot was brought down, the head pushed up, and the child extracted, during which the cervix seemed to tear behind. Fœtus was macerated. On attempting to remove the placenta manually the hand entered a cavity, and a much larger cavity was felt on right, extending up towards the liver. No placenta could be felt, but a piece of omentum came down and the intestines could be felt. Laparotomy was immediately performed. Free blood, but not much. Placenta was free and was removed first. An abdominal pregnancy was discovered, the sac apparently originating in the right broad ligament, extending out towards the left, and up on right towards the liver. The posterior lip of the cervix was torn, the tear extending downwards across the posterior fornix. The lower part of the uterus seemed very rotten and friable. Supravaginal hysterectomy was done, and the sac packed with gauze, the end being pushed out through the tear in the posterior fornix, and the cavity stitched together over the gauze. Two bimanual examinations had failed to reveal the presence of a small uterus, this condition being only discovered on laparotomy.—Dr. R. J. ROWLETTE suggested that, having regard to the fact that six weeks previously the patient, who lived in the country, had labour pains, the uterus at the time ruptured and allowed the greater part of the ovum to pass into the abdominal cavity, and that the uterus then involuted.—Mr. E. H. TWEEDY, Sir WILLIAM SMYLY, Dr. T. NEILL, Dr. V. J. MCALLISTER, and the PRESIDENT took part in the discussion.—Dr. JELLETT, in reply, said that the sac of the ovum was adherent to the intestine and omentum, which disproved Dr. Rowlette's

suggestion of the extrusion of the ovum through a rupture of the uterus six weeks before the patient came to hospital. Mr. Tweedy's previous myomectomy was done on the anterior wall of the uterus, and Dr. Jellett did not consider that it had had any effect in producing the condition met with. Neither Dr. Madill nor himself had the least idea that they were not dealing with an intra-uterine pregnancy until the abdomen was opened after the rupture of the gestation sac.

SECTION OF SURGERY.

Paget's Disease of the Nipple.—Carcinoma of the Breast.

A MEETING of this section was held on Nov. 28th, Mr. K. E. L. G. GUNN being in the chair.

Mr. R. C. B. MAUNSELL and Dr. J. T. WIGHAM communicated a paper on a case of Paget's Disease of the Nipple. Paget's original description was quoted, then an accurate clinical and microscopical description of the case was read. The communication was profusely illustrated with original coloured drawings and lantern slides of the clinical and microscopical appearances.—Mr. GUNN thanked Mr. Maunsell and Dr. Wigham for bringing forward the case. The rarity of the disease, he said, made the subject of greater interest, although more difficult to discuss.—Mr. A. J. BLAYNEY said that Mr. Maunsell regarded the case as of the nature of rodent ulcer. From this opinion he dissented. Another point of interest was that all cases observed terminated in cancer of the breast, and this also was contrary to the theory of rodent ulcer. It was pointed out that in most cases of rodent ulcer no enlargement of glands was to be found in the neighbourhood. Although he had an open mind on the subject he was inclined to the view that it was a case of malignant growth of the skin which subsequently spread to the breast.—Mr. H. STOKES also discussed the case.—Mr. MAUNSELL, in replying, said that before, at, and subsequent to operation a search was made for glands, but none were found. In his and Paget's description induration was not mentioned. The appearance or process of cells was more like that seen in rodent ulcer than anything else.—Dr. WIGHAM, replying, said that the case should be considered rather as a skin cancer than as rodent ulcer.

Mr. W. PEARSON read a paper on the Technique of Operation for Carcinoma of the Breast. He pointed out the principle on which modern radical operations for carcinoma are based, and communicated the following secondary principles of importance: (1) To avoid dissemination and wound-implantation of cancer cells during operative procedures; (2) to minimise hæmorrhage and shock; (3) to minimise the risks of infection; and (4) to avoid unnecessary mutilation and loss of function. The scope of the radical operation in favourable cases of carcinoma of the breast, in the light of Handley's investigations, was indicated, and the application of the secondary principles to the procedure discussed. The precise technique adopted was then explained with the aid of lantern slides, the special points on which emphasis was laid being: 1. That extensive removal of the fascial tissues with their contained lymphatics was the most important safeguard against recurrence. 2. That the operation, even in the making of the cutaneous incisions, should be regarded as a two-stage procedure—an axillary portion which should be first carried out, and, secondly, an abdomino-thoracic portion. 3. The use of the deep fascia over the clavicular fibres of the pectoralis major (which fibres might safely be retained in favourable cases) as a guide to the separation of the clavicular from the sternal divisions of the muscle. 4. The use of clamps on the pectoral muscles before division, both to act as retractors and to prevent possible dissemination. 5. The systematic exposure and securing of the blood-vessels in such a way that the operation was practically a bloodless one. 6. The necessity for additional drainage, besides the ordinary drain in the axilla, in certain cases. 7. The re-constitution of the axillary vault as the greatest safeguard against subsequent loss of function. 8. The importance of early movements of the arm.—Mr. GUNN emphasised the point that success in curing cancer of the breast depended more on early diagnosis than on the technique of the operation.—Mr. S. S. PRINGLE said that the procedure mentioned in the paper was the same as he had been carrying out for some years. A thing which impressed him with regard to this operation was the importance of keeping the upper ends of the incision well out of the axilla on account of the difficulty of properly sterilising the axillary fossa.—Mr. J. F. L. KEEGAN, Mr. STOKES, Mr. MAUNSELL, and Mr. C. A. BALL also discussed the paper.—Mr. PEARSON replied.

MANCHESTER PATHOLOGICAL SOCIETY.

A meeting of this society was held on Dec. 10th, Dr. A. Brown, the President, being in the chair.—Dr. Elliott gave an address on the human remains found on the site of the Roman cemetery recently discovered in Chester. The address was illustrated by lantern slides and autochromes. The situation and extent of the crofts, known in ancient times as "Lady Barrow's Hey," were described, the only portion remaining as meadow land until two years ago being the field adjoining the infirmary and known as the "Infirmary field." On this field two new wings in connexion with the infirmary extension are now being erected, and the excavations for their foundations have disclosed the site of a Roman cemetery. Some 30 burials have already been disclosed within a small area, in addition to a number of indiscriminate Roman interments at the back of the existing infirmary on the site of the new out-patient department, and in close proximity to the main site. The probable extent of the Roman city as contrasted with the present mural boundaries was discussed, showing that the site of the cemetery, although within the area of the modern walls, was certainly extra-mural in Roman times. The burials in nearly every case were in the boulder clay, superficial to which was a layer of virgin soil some two feet in depth, with a layer of surface soil of about the same depth above. A numbered plan of the graves was exhibited. Almost without exception the floor of the graves was sprinkled with a layer of finely divided, broken-up Roman tiles or bricks, mixed in many cases with charcoal. The varieties of burial were described and illustrated, comprising: 1. An arched tomb composed of sandstone blocks. 2. Tiled graves of rectangular box shape, composed of large roofing tiles forming the base, sides, and ends, three of which in one case bore the stamp of the Legion, Leg. XX. V. V., in each case on the surface of the tile looking inwards. The remains of male skeletons only were found in these "tiled graves." 3. Tiled graves composed of roofing tiles on each side meeting at an acute angle above, and thus forming on vertical section a triangular covering closed at the foot by another roofing tile. Outside the foot tile of one of those graves were found four vessels of Roman pottery (two of which were of Samian ware) with the bases perforated from without, and inside the grave under the feet of the skeleton were found the broken fragments of the bases with the potter's marks, thus throwing an interesting light on the graveside customs of that period. 4. A "cist" composed of sandstone blocks—the grave of a child. 5. Plain rectangular pits. In most cases numbers of roughly hewn sandstone "burrs" formed a superficial covering over the grave and surrounding area to prevent the inroads of wild animals. In one case a sheet of lead 16 inches wide covered the body from head to foot, being raised at the head end and curved over the feet. A number of skulls were exhibited showing the types of the inhabitants of Roman Britain: (1) the Mediterranean race; (2) the brachycephalic "Celt"; and (3) the extremely dolichocephalic skull of the type of Neolithic man. The origin and distribution of these races were discussed and illustrated. A number of interesting objects found in association with the burials were exhibited and illustrated, including brass coins of Antoninus Pius, Commodus, and a rare first century brass of Domitian; in several cases coins were found in the mouth, staining the lower jaw with verdigris; Roman lamp with maker's stamp "Fortis"; sandals with iron studs, those found in association with female skeletons being either devoid of studs or only provided with light ones; a stone "muller" with adhering vermilion and buff-coloured pigments associated with masses of fused bronze—in the grave of a male adult who had evidently been a worker in bronze; bone hair-pins and bones of animals; vessels of pottery and glass, some belonging to well-recognised types, others of rare occurrence; beads and fragments of bronze ornaments; oyster shells, &c. The almost universal occurrence of large iron nails, many with a projecting shoulder, was noted, and their significance discussed. In some of them adhering fragments of wood, which under the microscope could be identified as Pinus sylvestris, had been found in the later discovered burials. The stature of the individuals during life was estimated from the formulæ

worked out by Professor Karl Pearson and his pupils, as also the cubical capacity of the skulls. The peculiarities of the bones, both anatomical and pathological, were described. Several instances of metopism in the skulls and platycnemia of tibiæ were demonstrated. One example of hydrocephalus and one of exostosis in both external auditory canals were shown, as also a depression in the temporal bone indicating a healed mastoid abscess in another specimen. A typical achondroplasic skull of an adult was shown and the history and pathology of the disease indicated. Instances of caries in the well-worn teeth were few and far between, and instances of rheumatoid arthritis in the bones most exceptional. The early age at death was commented upon, and an illustration of an altar found in Chester erected by "Hermogenes, a physician," who is conjectured to have been physician to the Emperor Hadrian, was described as unique, the facilities for obtaining medical assistance at that early period in Britain being in all probability very remote. All the available evidence pointed to the fact that these burials were undoubtedly of the second century so far as excavated at present.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held on Dec. 5th, Dr. F. S. Palmer, the President, in the chair, Mr. J. E. R. McDonagh read a paper on the Biology of Syphilis. He maintained that after infection one or more spores gain access to the skin where they develop. When sufficient cycles which comprise the life-history of the leucocytozoon syphilidis have been completed the patient develops a sore. The spores gain access to connective tissue cells, which multiply enormously. The spore is a small body consisting almost entirely of nuclein, which as such is powerless, therefore it is obliged to enter a cell. A nucleus cannot develop without a nucleolus of the lecithin-globulin compound. This can only develop at the expense of the host, therefore it is necessary for the spore to enter a cell, which in the case of syphilis is a connective tissue cell. The lecithin globulin is built up from the simple protein of the protoplasm of the connective tissue cell. The lipoid protein forms a colloidal membrane in which the spore or trophozoote develops. In this envelope the nucleus either buds to form sexual nexozoitæ, or it divides and subdivides to form an asexual spore cyst. The former occurs in every case of syphilis, while the latter has only been found in the lymphatic glands from severe cases of the early generalised disease. An asexual spore cyst may bud to form daughter spore cysts, the parasite by this time being extracellular owing to the degeneration of the connective tissue cell. In the other mode of development of the trophozoite about 7 to 15 bodies are formed, each one having a lecithin-globulin envelope. When fully developed the cell bursts, the sexual mexozoites escaping to form male and female genitocytes, both motile. Later the female loses the blepharoplasts, becomes non-motile, and if about to be fertilised the nucleus takes a central position. The male genitocyte enters a large mononuclear leucocyte, where the three nuclear bodies increase in size and form a coil, and from each nuclear body a number of spirochætæ arise, ultimately breaking loose, when each can be recognised as a true spirochæta pallida. In extracellular development each nuclear body divides and subdivides; general bodies may break away *en masse*, ultimately breaking up into distinct coccus-like forms. Each coccus-like body contains two rods, which eventually become typical spirochætæ pallidæ. The intracellular development, according to the author, has been found in every syphilitic lesion so far examined, while the extracellular has only been found in chancres and condylomata. During fertilisation the spirochæta appears to enter the female nucleus wherein it becomes lost. In both cases the nucleus containing male and female elements migrates to the upper pole. After impregnation a polar body is shot out with great force from the cell, and again another after a minute or two. The nucleus then divides and subdivides into spiroblasts, which later form sporozoites. Mr. McDonagh then discussed the biology of the secondary and tertiary stages and of syphilis of the nervous system. With regard to the mechanism of protection against the leucocytozoon, he suggested that this was by means of the "oxygen-chain," the first link being the real blood corpuscles (containing free oxygen and a peroxydase), the next link a mast cell (its nuclei containing free oxygen and an activating ferment), and the last link the protoplasmic (containing oxygen but no peroxydase). The accelerator of the enzyme action is the element in the drug prescribed, such as arsenic, antimony, or mercury. He argued that as the protoplasm of plasma cells contains oxygen and lipoids, and metals accelerate an oxidising enzyme, possibly this enzyme abstracts oxygen from the lecithin, globulin envelope of the parasite, the envelope extracts free oxygen from the nucleus, with the result that if the ferment is powerful enough all free oxygen is abstracted and the parasite dies. The male gamete or spirochæta pallida is destroyed more quickly than other phases, and has also the strongest reducing action. In the author's opinion nerve cells are probably only influenced by spirochætæ. These being rich in unsaturated fatty acids snatch up the fats, lipoids, carbohydrates, and proteins of nerve cells. In the same way he maintains that nerve cells can take up substances, such as arsenic, and enable them to become part of their lipoids. Hence the nerve degeneration following injections of salvarsan into the theca.—The paper was followed by a discussion, in which the President, Staff-Surgeon G. B. Scott, R.N., Major Harrison, R.A.M.C., Mr. Aslett Baldwin, Mr. Rickard W. Lloyd, and Dr. Lloyd took part, and Mr. McDonagh then replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 28th, Mr. A. Ernest Maylard, the President, being in the chair.—Mr. Henry Rutherfurd showed: 1. A case of Plexiform Neuro-fibroma in a girl aged 8 years, with hypertrophic and pigmentary changes in the skin and some angiomatous patches, atrophy of muscles, and atrophy or rarefaction of bone as indicated by repeated fractures and verified by skiagraphs. 2. A case of Cystic Disease of Bone (upper end of humerus) in a boy aged 14 years, treated by free opening up and implantation of bone. The patient was shown, with skiagrams before and after operation. 3. Gall-bladders removed in conditions of Cholelithiasis (four recent cases), with microscopic preparations. 4. (With Professor J. H. Teacher.) The Spinal Column of a boy aged 6 years, the seat of multiple tuberculous foci (upper cervical, dorsal, and lumbo-sacral).—Dr. A. Louise McIlroy made a short communication on a case of Chorion-epithelioma and one of Myomata complicated with pregnancy, and showed coloured photographs. In the first case, that of a patient aged 30, a diagnosis of incomplete abortion was made, and on microscopic examination of the curettings Professor Teacher found chorion-epitheliomatous tissue. Panhysterectomy was performed with complete recovery. In the second case the patient, aged 30, had been married six years and was sterile. Dysmenorrhœa and menorrhagia had been present. On the onset of uterine hæmorrhage the patient was examined under an anæsthetic, and myomata with pregnancy were diagnosed. Supravaginal hysterectomy was performed, and on section of the specimen a four and a half months fœtus was seen. In the wall of the uterus were several myomata, one of which showed marked degenerative changes. The patient's health was markedly improved after operation.—Dr. J. W. McNee read a paper on Recent Work on the Etiology of Gall-stones. The views of the etiology of gall-stones which had been held for the last 20 years were those of Naunyn, who recognised two factors in the formation of all varieties of gall-stones—(1) stasis of the bile in the gall-bladder; and (2) inflammatory catarrh of the gall-bladder mucosa induced by micro-organisms. The work of Aschoff and his pupils, now accepted practically throughout Germany, had shown that three factors operated: 1. Stasis, by permitting the separating out of the constituents of gall-stones from the bile; the importance of this factor was seen in pregnancy and in general adiposity, two conditions in which the proclivity to gall-stone formation was well recognised. 2. Altered concentration of the constituents of the bile—i.e., increase of the stone-forming elements. It was now known that the amount of the cholesterin in the blood serum was above the normal in pregnancy, in diabetes mellitus, and other conditions of disease, and below the normal in tuberculosis, tumours, and acute fevers, except enteric; while the speaker, using the Windaus digitonin method in Aschoff's laboratory, had found in four cases of pregnancy amounts of cholesterin from 4 to 5 times the normal, and in a case of acute phthisis a month or two after delivery an amount eight times the normal. 3. Infection by micro-organisms, most commonly of the coli-typhoid group, which set up a

cholecystitis, with inflammatory exudate and increased mucous secretion from the gall-bladder walls and consequent addition of excess of lime salts to the bile. About 20 per cent. of all stones had, at first at least, no inflammatory factor in their origin. These were the pure cholesterin stones, crystalline in structure, occurring singly, often without symptoms, and due to the combined effect of stasis and excess of cholesterin in the bile. Infection of a gall-bladder containing such a stone led to an excess of lime salts in the bile and to the coating of the stone with a mantle of chalk and cholesterin deposited in concentric layers, and so to the formation of a "combination stone." Few cases of pure cholesterin stones escaped this inflammatory change, while 20 per cent. of all cases of inflammatory cholelithiasis passed through a non-inflammatory period. The commonest type of stone was the cholesterin-chalk or cholesterin-chalk-pigment stone, non-crystalline, of concentric formation, always multiple, often extraordinarily numerous, and originating in a gall-bladder which had become inflamed, and which might or might not have previously contained a stone of aseptic origin. Any truly rational treatment of gall-stones must not only aim at removal of the stones present, but must combat the stasis in the gall-bladder by adequate drainage, promote healing of the inflamed and often ulcerated gall-bladder wall, and take cognisance of the conditions which tended to increase the excretion of cholesterin in the bile.

WIGAN MEDICAL SOCIETY.—A meeting of this society was held on Nov. 25th, Dr. J. T. Shirlaw, the President, being in the chair.—Dr. George Jessel, tuberculosis officer for Wigan and area 14 of the county of Lancashire, read a paper on the Tuberculosis Dispensary. He said that on the next day there was to be opened in Wigan the first tuberculosis dispensary of its kind in the kingdom. It was to be under the joint authority of the county borough of Wigan and of the county of Lancashire, and was of an experimental nature, and would be watched with interest by other bodies. He pointed out the great and urgent necessity for a strenuous fight against tuberculosis, quoting the phthisis death-rate for England and Wales and the county borough. The dispensary idea was not new, neither was it called into being by the Insurance Act. The honour of being first in the land was due to Sir Robert Philip, of Edinburgh, and most of the later dispensaries had been largely modelled on this. The ideal tuberculosis dispensary should fulfil many duties. 1. It should be a centre for diagnosis. Dr. Jessel here emphasised the difficulty and desirability of early diagnosis. 2. It should act as an observation centre, bringing the tuberculosis officer in touch with contacts, suspects, &c. 3. A treatment centre in touch with all the various agencies for treatment. In this connexion he mentioned observation beds, which might be set up in various centres for the more careful observation of doubtful cases, sanatorial treatment, domiciliary treatment, isolation treatment for advanced cases so as to remove danger centres, surgical treatment for the various forms of surgical tuberculosis, after-treatment of cases returned from sanatoriums, &c. 4. A centre for research work. This must form an important part of the duty of a dispensary. 5. An information bureau and educational centre, from which would be distributed information regarding tuberculosis, its causes, mode of onset, &c., as only by educating people in this way could we obtain the intelligent coöperation of the people themselves, without which a great many early cases would be missed. 6. A centre for the after-care of cases recovered and recovering. There would eventually be in connexion with the ideal dispensary a farm colony or work colony, where the patients would work under proper care and supervision. Dr. Jessel next spoke of the ideal tuberculosis officer, who he thought should spend some time as a general practitioner. He then detailed his scheme to enable the dispensary and its officer to keep in touch with (1) the patient; (2) the medical officer of health, whose cordial support and coöperation were vital to the scheme; (3) the Insurance Committee; and (4) the panel doctors. He concluded by showing specimen cards to medical men in attendance, weight registers, simple temperature cards, &c., which he proposed to use in connexion with this work.—Several members present discussed Dr. Jessel's paper, and a hearty vote of thanks was passed to him for his address.—The biennial dinner of the society was held on Dec. 11th.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 3rd.—Dr. T. Graham Brown read a paper on Walking, in which he pointed out that animal progression was interesting not only from the standpoint of mechanics, but also from that of the central nervous control of the act, many of the problems of the physiology of the spinal cord being centred round the phenomenon. The dynamics of walking were considered and illustrated in the case of flight in the bird, and terrestrial progression in the case of the quadruped and in man. The characteristic rhythmic alternation of movement—e.g., flexion and extension in man—was emphasised. The physiology of the act was considered. It is not voluntary, since progression may be evoked after the removal of the cerebral control, as in Freusberg's "mark-time" reflex. Is it reflex? The problem presented centres round the question of the causation of the rhythmic alternation of movement. The methods of investigation were then described and the following theories advanced: (*a*) That the rhythmic alternation of movement is produced reflexly by the self-generated skin stimuli produced during the act by the pressure of the foot on the ground, &c. Objections to this view were discussed. (*b*) That the alternation is produced by the rhythmic inhibition of a maintained reflex; and that this rhythmic inhibition is self-generated by the movements of the active muscles stimulating the sensory organs in the muscles themselves during the act. (*c*) Experiments show that progression may take place after all the sensory nerves of the limbs have been destroyed. This shows that the rhythmic phenomenon is conditioned in the centres themselves and is not peripherally self-maintained. They also indicate that the rhythm results during a balance of equal and opposite activities in the centres. Therefore the theory has been propounded that the rhythm is conditioned during the equal and opposite activation of antagonistic spinal centres for the muscles of the limbs. Is this equal and opposite activation reflex—that is, caused by peripheral afferent stimuli? Against this is the fact that the act of progression may occur at a depth of narcosis at which the peripherally generated reflexes are abolished. The theory suggested by Dr. Brown is that the rhythm of progression is conditioned during an equal and opposite activation of the antagonistic spinal centres; that the rhythm is not a property of the nerve cell discharge as such; that it is fundamentally conditioned by the arrangement of the interconnexions of antagonistic nerve cells; that the equal and opposite activation of the antagonistic nerve cells may be in its turn conditioned by some such state as that produced by the "blood stimulus" in the respiratory centre; and that all the other factors emphasised in other theories are subsidiary in the normal act, helping and controlling it, but not fundamentally conditioning it.

BRISTOL HEALTH COMMITTEE.—At a recent meeting Mr. Colston Wintle was once more elected chairman of this committee, which has met 187 times, either in full committee or in subcommittee, during the past 12 months. Mr. Wintle gave a *résumé* of the year's work.

HOSPITAL ALMONERS' COUNCIL.—The annual meeting of the council was held on Dec. 10th at the Central Buildings, Westminster, Sir Malcolm Morris, Vice-President, in the chair. The secretary stated that 15 candidates for almoners' posts were in course of training. He referred to the appointment of an in-patient almoner at Great Ormond-street Hospital for Sick Children, and drew attention to the numerous appointments of assistant almoners as evidence of appreciation of the system on the part of those hospitals which had adopted it. In moving the adoption of the annual report Sir Malcolm Morris said that, after 48 years' experience of hospitals, he was convinced that there was no more important work being done in London than that of the almoners in supplementing the medical treatment provided by the hospitals. He pointed out that, unless the work of hospitals is linked up with that of charities outside their walls, patients cannot be enabled to benefit fully by the treatment they receive. He referred to the necessity of careful training for the work as provided by the council. He was of opinion that the public know far too little of the movement, and urging that it should be brought into much greater prominence, added that he would be glad to assist in this direction.

Reviews and Notices of Books.

Studies in Cancer and Allied Subjects: The Study of Experimental Cancer.

A Review by WILLIAM H. WOGLOM, M.D., Assistant Professor, Columbia University. Conducted under the George Crocker Special Research Fund at Columbia University. Vol. I. New York: Columbia University Press. 1913. Pp. 288. Price $5.

VOLUME II., dealing with the Pathology of Cancer, conducted under the Crocker Research Fund, was reviewed in THE LANCET of April 26th, 1913. In Volume I., which has been recently issued, we have a summary of the more recent experimental investigations of cancer. No attempt is made to give a critical *précis* at this time, since much of the work is so new, and ideas regarding the disease are so chaotic, says Dr. Woglom, that evaluation is well-nigh impossible. The author, however, ends on a more optimistic note, for, he says, "newer conceptions of malignant growth encourage the hope that at some time, far in the future though it may be, the dream of effectual interference with incessantly proliferating cells will become an actuality." Chemical studies have been omitted because a number of excellent reviews are in existence, and also because investigation in this field has thus far yielded but little of practical importance, while the bacteriological side has been neglected, because its discussion would amount to little more than a list of micro-organisms.

Having delimited his theme the author deals in succession with the following: A brief historical review; attempts to produce tumours; the earlier observations on the transmissibility of cancer; the transplanted tumour resistance; hypersusceptibility; the spontaneous tumour; tumours of a nature still undecided; and therapeutics.

From the earliest days in medicine cancer has been recognized to some extent as an incurable and fatal disease. Though the literature of experimental cancer seems to be a tangle of conflicting statements, there are a few threads which the author has endeavoured to disentangle and follow through. The mass of detail with appropriate references cited by Dr. Woglom is so vast that we must content ourselves with a brief summary of some of the main findings which may be regarded, he thinks, as "probably reliable," having received the support of a majority of those engaged in cancer research. It is to be remembered that there are mice and mice, and that what may happen in two groups of ten mice may not, and often does not, occur in a third series. The greatest amount of attention has been bestowed on mouse cancer, and the author expresses the view that there can be scarcely any doubt that the neoplasms of the mouse are entirely comparable to those of man. Malignant growths have been found in all classes of animals from fishes to mammals with one exception—viz., that no certain instance has yet been reported among the reptiles. There is some evidence to show that in mice there is an hereditary influence at work making mice of recent cancerous ancestry more prone to develop cancer than those in which the taint is more remote. Almost any spontaneous new growth in mice can be transplanted into other mice, and the propagation generally becomes easier in succeeding generations. Moreover, cancer is more readily transplantable into the animal in which it arose spontaneously than into any other. In addition, an animal cannot be immunised in any manner yet at command against the inoculation of its own primary tumour. These and other observations militate strongly against any parasitic theory of cancer. After a portion of a tumour is introduced into another host, the proliferation of the tumour is an example, not of an infection, but of a transplantation. The parenchymal cells of the resulting growth are derived, not from the elements of the new host, but from those of the transferred graft. These transplanted cells are nourished and supported by connective tissue and blood-vessels of the new organism.

A fact of prime importance in relation to all so-called cures of cancer is this, that propagable tumours are subject to fluctuations in growth energy. Indeed, they may grow progressively or disappear spontaneously. Under most favourable conditions the proliferative power of the cancer cell falls far short of that possessed by bacteria, and perhaps also of the cells of the developing embryo. Mice in which tumours have undergone partial or complete absorption are refractory to subsequent transplantation, either of the same or another growth. Immunity once induced cannot be transferred passively to other animals. There is a certain amount of evidence to show that natural resistance may be the outcome of hereditary transmission, but none to show that acquired immunity can be transferred. This brief summary, condensed from that of the author, postulates the present position of the question. Indeed, Dr. Woglom, after his most comprehensive survey and mature deliberation on the vast amount of detail he has passed in review, says: "It must be frankly confessed that so far, at least, the study of cancer, instead of affording an understanding of the nature of the disease, has but opened up new problems which were formerly not even conceived."

We express our grateful thanks to the author for his luminous summary of the present position of the question of experimental cancer.

Vaccine and Serum Therapy, including a Study of Infections, Theories of Immunity, Specific Diagnosis, and Chemotherapy.

By EDWIN HENRY SCHORER, B.S., M.D., Dr.P.H., Assistant Rockefeller Institute for Medical Research, New York City, &c. Second revised edition. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1913. Pp. 300. Price 12*s.* 6*d.* net.

THIS book proceeds on the usual lines of text-books on its subject. The first chapter deals with the general features of infectious disease, and the second with the different theories which have been put forward to explain the phenomena of immunity. The third chapter is devoted to specific diagnosis, including identification of organisms, agglutination, fixation of complement, opsonic determinations, and so forth, some empirical tests such as the cobra venom reaction being also mentioned, and some account given of inclusion bodies and filtrable viruses. The fourth chapter deals with specific methods of treatment by means of vaccines and serums, some account being given of the mode of preparing and standardising the latter and of the phenomena of serum disease. A few pages also are devoted to the use of leucocytic extract and normal serum. The fifth, last, and longest chapter contains an account of the practical application of the methods already described to the individual

infections, while an appendix is added on diagnosis, treatment, and prophylaxis of syphilis and malaria. There are a few illustrations, chiefly of temperature charts and apparatus.

The treatment of the subject throughout is adequate and the material is brought well up to date. In places the style seems unduly condensed, and we could have spared the brief accounts of the clinical features of some of the affections, which are not of much value, in order to have more detail on essential points. Thus the statement that "the only harm that can be done by careful tuberculin therapy exists when there are complicating diseases. Of these there are few of importance"—with no indication as to which are important—is not illuminating. Again, the assertion that all forms of tuberculin "produce good results in all types and forms of tuberculosis" is a wild overstatement, due probably merely to condensed or careless writing. The author has seen no marked good effects from the use of phylacogens. The author should make up his mind whether he wishes to call the organism of syphilis treponema or spirochæta and adhere throughout to one or other term. By the way, the phrase "two treponema" cannot be correct, though it may be a matter of individual preference whether the plural used is the English treponemas or the Græcolatin treponemata. It is fervently to be hoped that Noguchi's atrocities of nomenclature here adopted, sp. microdentium and macrodentium, will not survive.

The Poisonous Terrestrial Snakes of our British Indian Dominions (including Ceylon) and How to Recognise Them, with Symptoms of Snake Poisoning and Treatment.

By Major F. WALL, I.M.S., C.M.Z.S. Third edition. Bombay: Natural History Society. 1913. Pp. 149. Price Rs.3.

THE practical nature of the author's aim, partly indicated in the title, accounts for the neglect of the marine snakes in the volume before us. While Major Wall has not absolutely ignored the varied forms which frequent the seas that wash the shores of India and Ceylon, there is enough to be said about the numerous poisonous terrestrial snakes to justify any curtailment at the expense of their less important marine allies. The author enumerates 40 species of vipers and venomous colubrines as inhabitants of the political regions defined in his title, and to each species devotes a sufficient technical description and general notes upon appearance and habits. It should be easy enough for anyone of intelligence to identify a given species after mastering the clear directions devoted in an earlier chapter to the principal characters of scales and so forth, used in the differentiation of species from species and of genus from genus. These directions are accompanied by plain outline drawings of the head and tail of most of the marked types, which almost render a prolonged attention to the text unnecessary, so descriptive are they to the eye.

The zoological part of the book occupies 66 pages, the rest being devoted to snake poisoning and the symptoms and remedies thereof. In a condensed practical treatise of this sort disquisitions upon zoological matters of wider interest must not be looked for. The author has, however, devoted quite as much care to the preparation of the purely scientific side as to the more purely practical of his handbook. His statements of fact are trustworthy, and he has not ignored contemporary literature. The classification used is that crystallised by Dr. Boulenger into his British Museum catalogue of snakes, and only external characters are tabulated by Major Wall. For practical purposes this can still be done; but it is a little difficult to be sure whether it will be possible in the case of new forms which may turn up.

We are not at all surprised that this excellent manual has reached a third edition. Seeing how little in the way of records of new snakes has occurred since 1908, when the manual was first published, and having regard also to the energetic study on the part of herpetologists of many countries, it is not perhaps likely that the list displayed by Major Wall will be materially increased. This reflection gives us additional confidence in recommending the work.

Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord.

By ROBERT BING, Privat-docent for Neurology in the University of Basle. Translated by F. S. ARNOLD, M.B., B.Ch. Oxon. Second edition, revised and enlarged, with 73 illustrations. London: Rebman. 1913. Pp. 222. Price 10*s.* 6*d.* net.

WE have already favourably reviewed both the German and the English editions of this book. We now extend a welcome to the second English edition. A considerable number of emendations and additions have been found necessary; there is new material in the sections on the motor cortex, extracerebellar tumours, aphasia, apraxia, the pituitary and the pineal glands, &c. Some new illustrations are supplied, and a few of the old have been improved. In this new edition we consider that the needs of the student and the practitioner who is not a professed neurologist have been catered for in generous fashion.

Zur Psychopathologie des Alltagslebens.

(Über Vergessen, Versprechen, Vergreifen, Aberglaube und Irrtum.) By Professor Dr. SIGMUND FREUD, Vienna. Fourth, enlarged edition. Berlin: S. Karger. 1913. Pp. 198. Price 5 marks.

Professor Freud, as is well known to all workers in modern psychology, sees in everyday life innumerable instances of passion lurking behind trifling occurrences and incidents, instances of concealed or repressed mental processes behind the slips of the tongue, the mistakes, the forgetfulness, the misconceptions, to which all are more or less subject. That behind some apparently accidental and paltry occurrences repressed motives are at work is a truism which any introspective individual may readily discover for himself. Not infrequently the analysis of such incidents is psychologically very instructive, and the debt which psychology owes to the author is augmented by the critical and unflinching dissection of the human mind revealed in the book under consideration

Nevertheless, after re-reading this fourth edition, it is the duty of the critic to call attention to the author's tendency to overrate the significance of much of his material. The "will to believe" itself requires vigorous repression if we are to be saved from some of the exuberant interpretations which he would offer us. Thus we are told that the common experience of moving from one side to the other in front of an individual on the sidewalk, who makes the same movements so that progression is for the moment at a standstill, "sexuelle Absichten unter der Maske der Ungeschicklichkeit

verfolgt." When Professor Freud "accidentally" knocks a little marble statuette off his table there is a hidden meaning in the incident; the examination of such instances has convinced him that it is never the result of an accident. If, however, a domestic does the same, "so wird man an eine psychologische Erklärung hierfür gewiss nicht in erster Linie denken." Why "gewiss nicht"? These, and sundry other instances that might be quoted from the book, put a strain on the reader's willingness to endeavour to understand the author's argument. Much of what is offered by Professor Freud as explanatory is merely conjectural if not purely fantastic. The saving grace of common sense might, in some cases at least, find a simpler interpretation than that imagined by the ingenious subtlety of which Professor Freud is a master.

Handbuch der Vergleichenden Physiologie.

Herausgegeben von HANS WINTERSTEIN. Lieferung 37. Band III. *Physiologie des Energiewechsels.* Erste Hälfte. Jena: Gustav Fischer. 1913. Pp. 1133–1294. Price 5 marks.

Professor Biedermann brings to a close his long, laborious, and elaborate account of the physiology of the supporting and skeletal substances of the body with a fascinating account of the architecture of bone. Histology and architecture are considered, especially from the functional point of view, with a thoroughness and wealth of detail which leave nothing to be desired. The chemistry and development of bone conclude the article.

R. F. Fuchs, of Breslau, deals with the colour changes and the chromatic cutaneous functions of animals, a subject which attracted the attention of Aristotle himself. Beginning with the invertebrates, the chromatophores in the lower forms are first considered, then those of the mollusca, excluding the cephalopoda. To the colour changes and chromatophores of the cephalopoda alone nearly 100 pages, well illustrated, are given. This is by far the most comprehensive review that we know of on a fascinating subject. In the final pages the author begins his exposition of the colour changes in arthropoda.

LIBRARY TABLE.

The Principles of Evolution. By JOSEPH MCCABE London and Glasgow: Collins, Sons, and Co., Limited 1913. Pp. 264. Price 1*s.* net.—Mr. Joseph McCabe has a remarkable gift for dealing with a large subject in a small space. He gives in this little book a really good all-round description of the many various things connoted by the word "evolution." He explains what it is, and what effect its doctrines have had, not only in every conceivable field of study, but also on the thoughts, lives, and social behaviour of us all. He has to a great extent returned to first principles in narrating the facts and in dealing with the natural agencies of evolution, its range, and the various particular problems which at present engage attention. The chapter on natural selection is a clear exposition of two words of constant occurrence in newspapers and conversation, and very frequently misapplied. Mr. McCabe is the author of books describing the heavens and the earth on evolutionary lines, and to some extent this volume of the National Library is used as a supplement to previous writings. We recommend the book cordially. It is extraordinarily comprehensive, considering its size, and it is properly dogmatic—by which we mean to say that the need is recognised, if a book is to be small while its subject is almost indefinitely large, of saying certain things in a downright way without marshalling all the evidence for or against their truth.

The Practical Medicine Series. Vol. IV.: *Gynecology.* Edited by E. C. DUDLEY, A.M., M.D., Professor of Gynæcology, Northwestern University Medical School; and H. M. STOWE, M.D., Associate in Gynæcology, Northwestern University Medical School. Series 1913. Chicago: The Year Book Publishers. Pp. 230. Price 1.35 dollars.—This is one of a series of ten volumes issued at about monthly intervals and covering the entire field of medicine and surgery. They are published primarily for the general practitioner, and give a very complete *résumé* of the work done in the particular branch of medicine concerned. After chapters devoted to general principles, such as anæsthesia and operative technique and kindred subjects, the various infections and allied disorders of the genital organs are considered. In the same way a general survey is given of all the most recent papers in connexion with malformations and tumours, traumatisms, displacements and disorders of menstruation, and sterility. The value of the book is enhanced by the notes and annotations contributed by the editors, and the whole contains a great deal of valuable and interesting information on the recent progress of gynæcology.

Alimentary Toxæmia: Its Sources, Consequences, and Treatment. A Discussion opened by W. HALE WHITE, M.D., F. W. ANDREWES, M.D., VAUGHAN HARLEY, M.D., ROBERT SAUNDBY, M.D., Sir W. ARBUTHNOT LANE, M.S., and J. F. COLYER, M.R.C.S., L.D.S. London, New York, Calcutta, and Bombay: Longmans, Green, and Co. 1913. Pp. 380. Price, cloth, 4*s.* 6*d.* net.—The discussion on alimentary toxæmia at a series of special meetings of Fellows of the Royal Society of Medicine between March 10th and May 7th, 1913, was so fully reported in our columns at the time, Dr. Hale White's opening and closing addresses, together with the papers of Professor W. E. Dixon and Sir James Goodhart, being published in full, and an editorial review appended to the whole, that it is unnecessary here to say more than this reprint from the Proceedings of the Royal Society of Medicine is almost a text-book on the subject. The index will prove of particular service to those in search of information on this increasingly important topic.

Obstetric Aphorisms. For the Use of Students commencing Midwifery Practice. Eleventh edition. By JOSEPH GRIFFITHS SWAYNE, M.D. Revised and edited by WALTER CARLESS SWAYNE, M.D., B.S. Lond., M.D., Ch.B. Bristol. London: J. and A. Churchill. 1913. Pp. 216. Price 3*s.* 6*d.* net.—The editor, in response to many requests from friends, has come to the conclusion that there is still a place which a new edition of this work can fill with advantage, and therefore has revised and brought it up to date. The original form of the work has been retained as far as possible, but Dr. W. C. Swayne has endeavoured in his revision to retain the results of the immense practical experience and sound judgment of the author, even at the expense of modernity. This little book has no doubt proved useful to many hundreds of students since its first appearance some 20 years ago. In its modern dress it should be as helpful to present generations of students as it was to their predecessors.

MISCELLANEOUS VOLUMES.

Two books on medical missions are before us. In *Thirty Years in Kashmir* (London: Edward Arnold. 1913. Pp. 316. Price 12*s.* 6*d.* net.) Mr. ARTHUR NEVE, F.R.C.S. Edin., who, with his brother Ernest, is a surgeon to the Kashmir Mission Hospital at Srinagar, founded under the auspices of the Church Missionary Society, gives us an account of his life and experiences. Mr. Arthur Neve went to Kashmir in 1882 to replace Dr. Edmund Downes, retired for ill health. Medical matters, however, form but a very slight portion of the book before us, which is chiefly concerned with journeys in the interior of Kashmir and the surrounding territories of Little Tibet (i.e., Baltistan), Gilgit, Chitral, and the Karakorum range of mountains. The book is somewhat sketchy, though it would probably be difficult for anyone who had not a vastly picturesque pen to convey to an ordinary reader the emotions called up by the awe-inspiring scenery of vast groups of mountains. "Surely the gods live here," said Kim, when he drew near to Kedarnath, one of the giants of the range, and the silences, the spaces, and the majesty of the land evidently affected Mr. Neve, although he gives but superficial descriptions. When he was in Gilgit Mr. Neve paid a visit to Captain (now Major) McCarrison's hospital, in which he was naturally deeply interested, and he rightly pays a warm tribute to Captain McCarrison's work on goitre, many reports of which have appeared in our columns. Concerning it Mr. Neve says: "Work such as his ranks, in my mind, as medical mission work, and must be of very real value in winning the liking and respect of the people for their European rulers." Mr. Neve modestly says next to nothing of his own work, and when on p. 242 he gives an account of three cataract operations performed under great difficulties in Little Tibet he omits to tell us the ultimate results; however, as is well known, the results of cataract operations by a skilled operator upon almost any native of India and the provinces to the north of it are extraordinarily good despite the want of skilled after-treatment. The book, when it comes to a second edition, would be much improved by a good map, for the sketch map appended is but of little use. Even with its deficiencies the work is worth reading as an introduction to a territory unknown to most of us.——*The Appeal of Medical Missions*, by R. FLETCHER MOORSHEAD, M.B. Durh., F.R.C.S. Eng. (London and Edinburgh: Oliphant, Anderson, and Ferrier. 1913. Pp. 224. Price 2*s.* 6*d.*), is an earnest appeal for the institution and support of medical missions, backed by many illustrations of the value of the work carried on by existing missions. To those who look back to primitive Christianity as a model for all time medical missions must appeal with special force, for the first missionaries on record—namely, St. Paul and St. Barnabas—healed the sick and afflicted at Lystra and were thereupon considered to be gods in the likeness of men. Not the least valuable portion of Dr. Moorshead's book is the chapter dealing with the Failure of Medical Missions, in connexion with which he wisely says: "Thoroughness and efficiency should characterise every aspect of the work. Apart from these qualities, medical missions—we say it advisedly—will not pay." This chapter on Failure is naturally followed by one dealing with the Training of a Medical Missionary, which contains much sound advice. It is no part of our duty to discuss the theological side of the training, but we can at least say that we entirely approve of one canon laid down by Dr. Moorshead—namely, that the medical missionary should have "an intelligent acquaintance with the religious beliefs of the people amongst whom he is to labour." Christian missions are unfortunately carried on by very varying divisions of Christianity and are accordingly hindered by many unhappy divisions, but as regards the medical and scientific side of the matter would-be missionaries to whatever division of the Church or to whatever sect they belong will find profit in reading Dr. Moorshead's book.——The Red Cross organisation may be described as in a sense almost a medical mission—at any rate, of humanity. In *The British Red Cross in the Balkans* (London, New York, Toronto, and Melbourne: Cassell and Co. 1913. Pp. 68, with 160 illustrations. Price 1*s.* net) we have some indication of the way in which the £40,000 subscribed by the public were spent in the humane work, and of the difficulties of medical service in modern warfare. The pictures are prefaced by a short introduction, and a frontispiece illustrates the presentation of medals to the Balkan war nurses of the British Red Cross Society by Her Majesty Queen Alexandra.

JOURNALS AND MAGAZINES.

The Philippine Journal of Tropical Medicine, Section B., Nos. 3 and 4, 1913.—The first of these numbers opens with an interesting account of the intestinal parasites encountered in 500 consecutive necropsies, with reports of cases by Dr. B. C. Crowell and Dr. R. W. Hammach, respectively associate professor and instructor in pathology and bacteriology in the University of the Philippines. These observers found ascaris lumbricoides in 41·2 per cent. of the cases, trichuris trichiura in 34·4 per cent., and hookworm in 16·6 per cent. One case of ascaris in the appendix was found, and in two clinical cases of appendicitis trichuris was discovered in the appendix.—Captain Edward B. Vedder, of the United States Army Medical Corps, and Dr. Robert R. Williams contribute a description of some experiments concerning the beri-beri preventing substances, or vitamines, contained in rice polishings. They confirm the observations of C. Funk by isolating a crystalline base from an extract of the polishings. They also obtained confirmatory evidence of the hypothesis they had formerly advanced—namely, that wet beri-beri and dry beri-beri are two distinct conditions, each being caused by the deficiency of a separate vitamine.—Mr. M. Bruin Mitzmain, of the Veterinary Division of the Bureau of Agriculture, Manila, writes upon the biology of the Tabanus striatus fabricus, the horse-fly of the Philippines, his paper being illustrated with a series of descriptive plates; and the same contributor furnishes also an article on the mechanical transmission of surra by this fly. It appears that this is the first time that the transmission of surra by this species of tabanus has been recorded.—Dr. P. K. Gilman, of the General Hospital, Manila, gives an article on axillary teratoma, with illustrations.—Mr. W. H. Boynton supplies a note on "strangles," or horse distemper, in the Philippines, and arrives at the conclusion that the affection is widespread among the horses of the islands.—Lastly, Dr. Oscar Teague, supplementing his previous work, gives a further note upon the influence of atmospheric temperature upon the spread of pneumonic plague.

The second of the two numbers is wholly filled by an article entitled, "An Experimental Study of Entamœbic Dysentery," by Dr. Edward Linwood Walker, in collaboration with Dr. Andrew Watson Sellars, both of the Biological Laboratory, Bureau of Science, Manila. These investigations were undertaken in order to determine experimentally the etiological relationship of different species of amœbic organisms to endemic tropical dysentery, and included 60 feeding experiments with the different species of amœba and entamœba which have at one or another time been implicated in the production of the disease. It is claimed by the authors that the experiments have been of a kind never hitherto performed, and that as a result information of the greatest value for the diagnosis, treatment, and prophylaxis of entamœbic dysentery has been obtained.

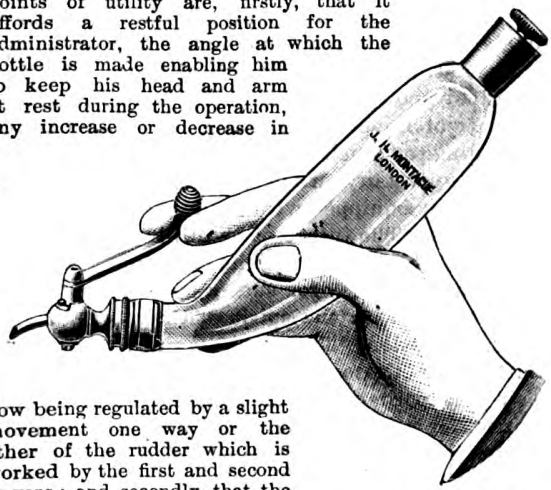
Biometrika (Vol. IX., Parts III. and IV. October, 1913. Issued Nov. 8th, 1913). Edited by KARL PEARSON. Cambridge University Press. Price 20*s.* net.—We are amazed at the wealth of painstaking research that is enshrined in each issue of *Biometrika*. The issues before us contain an article on Anomalies of Pigmentation among Natives of Nyasaland, by Hugh Stannus Stannus, which is described as a contribution to the study of albinism. W. R. Macdonell follows with an interesting paper on the Expectation of Life in Ancient Rome and her Provinces, a note on which appears elsewhere. George McMullan and Professor Karl Pearson have a second paper on the Inheritance of the Deformity Known as Split-foot or Lobster-claw. Kathleen V. Ryley and Julia Bell, with the assistance of Professor Pearson, give a study of the Nasal Bridge in the Anthropoid Apes and its Relationship to the Nasal Bridge in Man. J. Arthur Harris discusses the Calculations of Intra-class and Inter-class Coefficients of Correlation from Class Movements when the Number of Possible Combinations is Large. M. Greenwood jun., and J. W. Brown, from the Statistical Laboratory of the Lister Institute, publish a second study of the Weight, Variability, and Correlation of the Human

Viscera. D. H. de Souza describes a series of painstaking investigations regarding the Measurements of the Pelvis with Special Reference to Obstetric Prediction, and arrives at certain formulæ for finding the obstetric conjugate and the transverse diameters in the living subject.

New Inventions.

AN IMPROVED URINE SPECIMEN GLASS.

WE have introduced an improved specimen glass which will be found useful in hospitals and by insurance examiners and others who frequently examine urine. The advantages are: (*a*) a small calibre, so that about an ounce of fluid will freely float an ordinary urinometer; (*b*) a blunt conical bottom to enable sediment to be collected, and for ease of cleaning; (*c*) a funnel-shaped top to hold filter paper, thus obviating the use of a funnel; and (*d*) the wide and level top allows the glass to safely stand inverted for drainage.



The glasses are made and supplied by Messrs. Down Bros., St. Thomas's-street, London, S.E.

ARTHUR H. RIDEAL, M.D. Aberd.
W. OLIVER BEDDARD, M.R.C.S. Eng., L.R.C.P. Lond.

A NEW ETHER DROP BOTTLE.

THE general appearance and method of using this bottle can be gathered from the illustration. Its chief points of utility are, firstly, that it affords a restful position for the administrator, the angle at which the bottle is made enabling him to keep his head and arm at rest during the operation, any increase or decrease in flow being regulated by a slight movement one way or the other of the rudder which is worked by the first and second fingers; and secondly, that the anæsthetic can be commenced very gradually, at any pace from ten drops to the minute upwards. I find this gradual induction very useful in the case of infants and children, as it enables the respiratory tract to accustom itself to the ether by degrees, and consequently there is no coughing or holding of breath. Another small point is that there is little or no waste of anæsthetic as there must be when it is poured on in larger quantities. I have used this bottle for four years at the Evelina Hospital with most satisfactory results.

The makers are Messrs. Montague of New Bond-street, London, W.

DOUGLAS JACKSON, M.R.C.S. Eng., L.R.C.P. Lond.

Harley-street, W.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

AN ordinary meeting of the Council was held on Dec. 11th, Sir RICKMAN GODLEE, the President, being in the chair.

The PRESIDENT reported his attendance at Chicago on Nov. 13th, on the occasion of the First Annual Congregation of the American College of Surgeons, and he also stated that he had visited the University of Toronto, and had received the degree of LL.D.

The SECRETARY reported the death on Dec. 7th, at the age of 83, of Mr. Sydney Jones, past member of the Council. A vote of condolence was passed, expressing the sympathy of the Council with the family and their appreciation of the late Fellow's services to the College.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that at the examination concluding on Nov. 14th 129 candidates were examined, of whom 44 were approved and 85 rejected.

It was resolved to grant diplomas of Fellowship to 28 successful candidates.

It was resolved to grant diplomas of the Licence in Dental Surgery to 54 successful candidates.

Mr. W. G. Spencer was re-elected a member of the Court of Examiners.

A report from the committee on the annual report of the Council was received and approved. It contained the following statements: "With regard to resolutions Nos. 1 and 2 the committee do not think that the Council are called upon to reconsider their decisions respecting the subjects to which they refer. As regards resolution No. 3 the committee are of opinion that the satisfactory financial position of the College at the present time is sufficiently evident to any Fellow or Member who studies the published accounts."

A letter was read from Lord Sydenham to the President stating that "the Royal Commission on Venereal Diseases are desirous of obtaining the coöperation of the Royal College of Surgeons in securing the best evidence available on the questions referred to the Commission for their investigation, and they would welcome any suggestions from you as to suitable witnesses to be called, especially respecting the more indirect effects of syphilis in producing organic disease and upon the subject of remedial measures." In reply the Council nominated Mr. D'Arcy Power, surgeon to St. Bartholomew's Hospital, Mr. F. Richardson Cross, president of the Ophthalmological Society of the United Kingdom, and Mr. S. G. Shattock, pathological curator of the Royal College of Surgeons of England, to give evidence on these matters.

A letter was read from Sir Henry Morris, reporting the proceedings of the General Medical Council at its late session. The best thanks of the Council were given to Sir Henry Morris for representing the College on that Council.

The JUNIOR VICE-PRESIDENT reported the delivery of the Bradshaw Lecture on Gunshot Injuries of the Arteries by Mr. G. H. Makins, C.B., on Dec. 5th. The best thanks of the Council were given to Mr. Makins for his lecture and he was requested to publish it.

The College, including the museum and library, will be closed from the evening of Wednesday, Dec. 24th, until the following Monday morning.

A MUNIFICENT THANKOFFERING.—To mark the coming of age of their elder son, Lord Titchfield, and to celebrate their silver wedding, the Duke and Duchess of Portland have offered to Mansfield Hospital a sum of about £5000 to liquidate the debt on the King Edward memorial wing of the institution.

BRISTOL GENERAL HOSPITAL.—At two recent functions, the nurses' prize-giving and the annual meeting of the ladies' needlework guild, allusions were made in terms of deep satisfaction to the recent election of Mr. George Wills to the presidency of the hospital. At the latter meeting it was stated that the guild had contributed over 4000 articles of clothing, bed-linen, &c., as well as a sum of £112. Both of these figures represent the highest totals yet attained.

THE LANCET.

LONDON: SATURDAY, DECEMBER 20, 1913.

The University of London: The Question of Site.

Mr. J. A. PEASE, President of the Board of Education, on the occasion of the Founders' Day Celebration at Birkbeck College on Dec. 10th, made a statement, in continuation of previous pronouncements,[1] on the subject of the future of university education in London which was full of importance for a great number of our readers. For questions of medical education in the metropolis, the centre for the administration of the work of the Royal medical corporations, and the seat of a famous group of hospitals and of a university owning distinguished medical graduates all over the world, have definite interest for the majority of our profession. Mr. PEASE placed in the front of his observations the question of the formation of a university quarter, and it is perfectly clear that much of the immediate future of the University of London may depend upon the selection of a site for any new buildings that have at once to be erected. A distinct recommendation of the recent Royal Commission, as well as the general spirit of the report of that body, makes the acquisition of a site whereon a university quarter can be properly developed a necessity, and it will be necessary in choosing that site to estimate carefully, not only what is wanted at once, but what will be wanted when, under revivifying processes, expansion along lines that are as progressive as academic begins to take place.

The three things to be considered about any site that may be available are the opportunities that it offers for such development, economy in price, and dignity in position; and we put them in what we consider to be the order of their importance. It must never be forgotten that the Report of the Royal Commissioners on University Education in London did not plan in their recommendations so much a machine to start at once in perfection as one which, while discharging its functions now with all the efficiency which a considerable series of compromises can allow, should provide for the possibilities of future expansion. The Commissioners recognised that there must be a great deal of harmony between opposing interests before a scheme working to something like the general satisfaction of all concerned could be set in motion, and it seems to us essential that the same reasonable frame of mind must be employed in choosing the *locale* of the new University quarter. It must be selected with an eye to the possible rearrangement of some existing institutions and to the addition of others. Therefore we regard the project of making over Somerset House, the most distinguished palace in London, to the University with considerable distrust, although the idea was on Tuesday last approved by the London County Council. It does not seem to us that a quadrangle of no vast size, inexorably bounded on three sides by main roads of the utmost importance and on the fourth side by premises whose confiscation is unthinkable, the whole standing on one of the most valuable pieces of land in the world, makes a good central site for a university whose intention it is to develop in many directions. Somerset House is dignified, but dignity is the third necessity only, and need not be bought at a high price when it will be within the power of the University to achieve it by well-directed effort, instead of buying it ready made. No one suggests that the Somerset House site could possibly be economical. In balancing the claims of the suggested site between Westminster Bridge and Waterloo Bridge with those of the two suggested sites in Bloomsbury, the question of price must play a part in the decision. Where the London County Council is the owner of a possible site generous terms might be obtained, for the Council bears part of the burden of supporting the University of London already, and takes a deep interest in its prosperity; while it will naturally be glad, in fulfilment of its æsthetic duties towards the citizens at large, to fill a conspicuous spot with the new buildings of such an institution as the University. Dignity is a great thing, and no institution more strongly than a great university has a right to demand the prestige of dignity in the outward symbols of its corporate life. But the University of London can attain to its dignity by not standing too much thereon. There is no necessity for a university, when making a new start, to be completely equipped with palaces in commanding positions. The future of the University should not be risked by any waiting for this kind of endowment, and delay for such a purpose would be out of keeping with the spirit of the report of the Royal Commission. The most dignified university buildings are those which have acquired their pleasing and perhaps imposing character by honourable use for the best purposes and by gradual additions to meet growing wants. Whether Bloomsbury, Kensington, Lambeth, or elsewhere houses the new University quarter, the essential thing is that room for evolution be found. We cannot believe that the teachers in the various faculties will desire in any majority to remain at Kensington.

Convenience must be regarded as a part of economy. Land whereon to build a University quarter would certainly be cheaper in Streatham than in the Strand, in Barnet than in Bloomsbury. But the new University quarter must have an academic and educational reason for its position; proximity to potential playing fields would not make an otherwise inaccessible site economical, even

[1] THE LANCET Nov. 22nd, 1913, p. 1482.

though it were cheap. The Faculty of Medicine, when higher medical education in London is organised, may have less immediately to say to the locality of the central buildings than any of the other faculties, because higher medical education will be undertaken in close connexion with the hospitals. The site of the metropolitan hospitals is in the majority of cases fixed for the time being; while when a change of locality is forced upon any of these great charities other considerations must outweigh the claims of academic or civic pride in fine buildings prominently placed. Medicine and surgery can be intimate parts of a university education if the hospitals that are essential to a medical faculty are connected to the necessary extent of intimacy with the university; geographical intimacy is not so much required. But the medical faculty, being one of the most important constituents of the University of London, is on general grounds deeply anxious that the University should possess an adequate central home; and it may be part of the give-and-take demanded of some of the medical schools and scientific institutions that they should acquiesce, in return for corporate advantages, in the choice of a central site of which they do not wholly approve.

Precautions Concerning Celluloid.

THE Departmental Committee which was appointed in October, 1912, "to inquire and report as to the precautions necessary in the use of celluloid in manufacture and the handling and storage of celluloid and celluloid articles" issued its report last week, and we may say at once that it shows a very intelligent and impartial treatment of the manifold questions which the subject presents. The chairman, the Earl of PLYMOUTH, was supported by men well qualified to deal with the particular points which needed inquiry in regard to rendering the handling and storage of celluloid freer from danger than has been the case in the past. The committee included Captain MAURICE B. LLOYD, H.M. Inspector of Explosives; Dr. JAMES S. DOBBIE, the principal of the Government laboratories; Mr. H. M. ROBINSON, Deputy Chief Inspector of Factories; Mr. EDWIN O. SACHS, chairman of the executive of the British Fire Prevention Committee; and Mr. J. OLLIS, chief officer of the public control department of the London County Council; Mr. C. G. MARKBREITER, of the Home Office, acting as secretary. As the minutes of evidence show, many pertinent questions were put and the answers given were in the main instructive. The witnesses were frank and also well selected, including amongst them representatives of the trade in celluloid, many persons of scientific standing, and officers of fire brigades. The committee visited premises in London and elsewhere to see the conditions under which celluloid is made, worked, and stored. They also made a practical study of the operation and effect of the regulations in force in France and Germany. Dr. DOBBIE carried out many important experiments as to the nature and properties of celluloid, while the British Fire Prevention Committee placed at the disposal of the Departmental Committee the results of an investigation made by them.

We have given considerable practical attention to this matter. The danger in the use of celluloid was prominently brought into notice in THE LANCET early in the year 1892, when a number of experiments were made in our laboratory illustrating the alarmingly inflammable nature of the substance. We believe these were amongst the earliest experiments published calling attention to the risks which the use of celluloid articles entailed. In 1898 a serious incident was brought to our notice in which a hair-fastener or comb made of celluloid had ignited in contact with hot tongs, used in the curling of the hair. Several experiments were made with similar hair combs obtained in the open market, and the results were of so startling a character that we were led to urge that manufacturers should be compelled to stamp plainly on every article made of or containing celluloid the words "highly inflammable." In 1902 we repeated this warning in view of a report which was published in THE LANCET on "Burns from Celluloid," by Sir ALEXANDER OGSTON, Regius professor of surgery in the University of Aberdeen. Since the date of our work the applications of celluloid have increased very much. It has been estimated that celluloid in one form or another is to be found in between 40 to 50 per cent. of the shops in certain districts of London. A list giving the uses to which celluloid is put, if extracted from the catalogue of a big shop, would contain some 200 articles classified under the headings of (1) dress and personal; (2) fancy goods; (3) musical; (4) sports and toys; (5) stationery and office; (6) scientific and surgical; (7) factories and shops; and (8) lacquers. This list, however, does not include the cinematograph film. This industry shows an enormous development. In June, 1912, there were 32 producers of films in this country, and there were 80 firms engaged in renting or letting out films for hire and between 4000 to 5000 cinematograph theatres. Stocks increased and the celluloid danger grew in magnitude. Accidents were no longer confined to small domestic occurrences, such as were reported in THE LANCET 20 years ago; they became classed in 1900 as serious fires involving the loss of many lives. A terrible disaster last year in Moor-lane in the City of London, in which nine girls perished in the flames of a fire started by celluloid, roused a general feeling of indignation that such awful liabilities should be allowed to exist, and that apparently no attempts had been made to bring the storing and manufacture of celluloid under a system of public control. The demand for an official inquiry was made, and was promptly acceded to, with the result now before us.

We hope that the recommendations of the Departmental Committee will receive equally speedy

attention, so that safeguards may quickly be provided in connexion with the use of celluloid in manufacture, and the handling and storage of celluloid and of all articles made from it. The danger to the purchasing public, the danger in shops in which celluloid articles are exposed for sale, the danger involved in conveyance, the danger of warehousing large stocks, the danger of the cinematograph film, have all received careful attention at the hands of this committee, and the precautions which are laid down seem to us to be reasonable and to be warranted by the teaching of disastrous experiences. We agree that all domestic articles made of celluloid should be declared. The committee consider that they should be marked with the words "Celluloid, inflammable." We made the same suggestion 20 years ago. We agree that warnings should be issued to shopkeepers as to the dangerous properties of celluloid. Often at Christmas time many shops swarm with celluloid toys that the immediate present is a date when such a warning should be issued. We agree also that there should be certain restrictions in regard to storage. There was actually found on one set of premises in London over a ton of celluloid, while the site of storage has its risks as well as the bulk, for films have been secreted underneath an hotel and in domestic flats. It is evident that the conditions under which this business is carried on are quite unsatisfactory. Celluloid is an exceedingly useful substance, and has been turned to human account with advantages in very many directions, but it can never be allowed to masquerade as an innocent material. There is much ignorance of the dangerous nature of celluloid which this report should go far to remove, and the recommendations in it, for which we may claim to have laid some foundation, should be adopted.

Annotations.

"Ne quid nimis."

THE ISTHMIAN CANAL AND DISEASE.

IT is now accepted that without our present knowledge of malaria the Isthmian Canal could not have been constructed, but it is less well understood that the making of the canal has furnished opportunity for acquiring greatly increased information about the disease, especially with regard to its epidemiology and administrative control. Some of the valuable results obtained are to be found in a small pamphlet issued by the Isthmian Canal Commission and written by Dr. S. T. Darling, the chief of the laboratory of the Board of Health.[1] It is a short pamphlet, but it contains the results of much work and is of interest to the physician, the administrator, and the investigator. The investigator will find an account of the 11 species of anophelines found during the past eight years in the canal zone. Of these the most important as a transmitter of malaria at the present time appears to be anopheles albimanus. The methods found best for the collection of larvæ, the breeding and feeding of mosquitoes, and how best to secure biting and infection are described. It was found that at least 50 per cent. of the parasites were destroyed in the mosquito by the polymorphonuclear cells of the ingested blood, and that the food contents of the gut of the insect greatly affected the development of the parasite. The physician will learn that though a patient is treated with quinine the amount present in the blood does not prevent normal development in the mosquito, but there is a steady diminution in the number of the parasites, whether crescents or gametes, in the circulating blood, accompanied by an increase in large mononuclear cells. It was found that a treated patient should not be discharged until the number of gametes was reduced well below the limit of infectiousness; a patient with 12 gametes per c.mm. could act as a carrier, and these cases were of the utmost importance to the administrator in delimiting malaria. An investigation into latent untreated malaria which contributes so largely in every tropical community to the preservation of the malarial parasite was made; it was found that about 10 per cent. of the inhabitants were infected. Of interest to the administrator also are the results of experiments on the efficiency of larvicides, the mesh and material of wire screening, the effect of salt and sea water on larvæ, and the action of various agents which may be employed to destroy the food of the larvæ. The work on malaria does not preclude investigation of other diseases, as is evidenced by the interesting account of entamœba tetragena by Dr. Darling,[2] but enough has been said to show how fruitful is the work of the Department of Sanitation in the Canal Zone.

THE PHYSICIAN IN ENGLISH HISTORY.

TO the student of medical history the subject of the medical man outside of medicine is one of great interest and full of suggestiveness. The very nature of the training in medicine impresses upon a man—one, that is, who is in any sense "called" to the study of medicine—a character, a mode of thought, a particular outlook, which more or less insensibly colours his attitude towards all the relations of life. Thus it arises that the careers of medical clerics, medical lawyers, medical administrators, medical soldiers and sailors and adventurers, medical artists and writers of imaginative literature, have formed subjects of collective study at different times. A recent and most valuable study of this character was the Linacre lecture[1] this year, by Dr. Norman Moore, in which the author endeavoured to trace the influence exercised by the physician on the nation at large, other than that arising out of his scientific discoveries and their direct application. Starting with Cynifrid, who is mentioned in Bede's "Historia Ecclesiastica Gentis Anglorum," as the medical attendant on the Abbess Etheldreda of Ely (obiit 679), and as being present at her disinterment 16 years later, Dr. Moore discusses the death of William the Conqueror,

[1] The Physician in English History (Linacre Lecture, St. John's College, Cambridge). By Norman Moore, M.D. Cambridge: University Press. 1913. Pp. 87. Price 2s. 6d. net.

the physician ecclesiastics of the Middle Ages, the establishment of the London College of Physicians in 1518 by King Henry VIII. at the instance of six physicians, of whom the prime mover was Linacre, and the foundation of the Royal Society. He refers to Francis, Caius, Sir Hans Sloane, William Gilbert, Sir William Petty, Thomas Lodge, Cowley, Garth, Arbuthnot, and others to illustrate the share taken by members of the medical profession respectively in the revival of Greek learning, in additions to science—not merely medical science, but science in general—in establishing hospitals, in building up medical education, and in contributing to English literature. Such studies are not only very interesting, but are of real value in making us comprehend the stability of our foundations as an art and a science.

CHRISTMAS AND BURNING ACCIDENTS.

AS Christmas approaches we would remind parents and organisers of seasonable entertainments of the terrible accidents which have arisen in the past owing chiefly to the inflammable nature of cotton-wool. Children and others dressed up in muslins and light materials and decorations of cotton-wool to imitate snow, should not be allowed in any room where there are unguarded fires or unprotected lights of any kind. Youths of the present day light cigarettes at the smallest opportunity and on occasions which 20 years ago would certainly not have been made use of for smoking, and those indulging in this silly habit should be sternly checked in any room or place where costumes are being worn of the nature indicated. The safest plan is, of course, for parents to insist that their children shall not take part in entertainments at which the usual inflammable materials are present. This may be a counsel of perfection, but, at any rate, reasonable precautions can be taken, and means of extinguishing fire, should it break out, can be provided.

THE URINARY REACTION OF WEISZ.

THIS reaction was originally brought into notice in 1910 as preferable in regard to simplicity to the diazo-reaction of Ehrlich. It has the further advantages that it is never observed in normal urines, and is not simulated by various drugs such as creasote, laudanum, and naphthalene, as may be the case with the diazo-reaction. Neither is it nullified by substances artificially added to the urine. The technique consists in diluting the urine with twice its bulk of distilled water; three drops of a 1 per 1000 aqueous solution of permanganate of potash are added and the mixture shaken. If the reaction is negative the liquid does not change colour, or only becomes slightly brownish; if positive it assumes a greenish yellow or golden colour. According to Weisz the reaction indicates that the patient is the subject of tuberculosis in an advanced stage, so that it has a double significance, diagnosing that the disease is tubercle and prognosing that the state of the patient is grave. Dr. E. Salustri has recently published in the *Policlinico*[1] the results of his investigations on this subject made in Professor Ferrannini's clinic at the University of Camerino. He found that when in a patient who was seriously ill but the exact nature of whose disease was doubtful the urine showed the Weisz permanganate reaction in a pronounced manner, this fact points to the definite conclusion that the disease is dependent on Koch's bacillus and is in a very advanced stage. On the contrary, the absence or feeble degree of the reaction excludes tubercle as a cause without impugning the marked gravity of the disease. When the affection from which the patient is suffering is of medium or slight gravity the presence of this reaction does not afford precise evidence that it is due to tubercle, but is useful as a confirmation that the disease, whatever its nature may be, is of little gravity. In other words, the significance of the reaction in respect to the diagnosis and prognosis of tubercle is much more important and marked in patients in whom the reaction is either invariably absent, or, on the other hand, is constantly present in a marked degree.

THE LAST ILLNESS OF MICHAEL BARCLAY DE TOLLY.

THE recent celebrations of the centennial of Napoleon's collapse after the Russian campaign have again brought into prominence the leading personalities of that period. Eminent among these was Prince Michael Barclay de Tolly, whose Fabian policy was largely responsible for Napoleon's inability to crush the Russian army. In the *Petersburger Medizinische Zeitschrift* of Nov. 15th Dr. Arved Bertels has discussed the nature of Barclay de Tolly's last illness, his sources of information being the reminiscences of an eye-witness and an account of the necropsy found in the Government Library in Riga. The reminiscences published in 1887 were by Barclay de Tolly's adopted daughter, who was 14 years old when she accompanied him on his last journey in 1818. At this date he had been granted two years' furlough to travel abroad for his health. During his journey he had frequently to stop his carriage on account of severe pain in the chest. Supported by his physician, he would walk a few steps, and when the pain had passed he would continue his journey. After travelling through Riga, Memel, and Tilsit he had almost reached Insterburg when his physician declared him incapable of advancing farther. He was lodged at a small hunting-lodge, where he died on the same night. Physicians were summoned from Königsberg and Berlin to embalm the body. Barclay de Tolly died on May 16th. In a document dated May 29th, 1818, Dr. Fahrenhorst, who signs himself "Konigl. Preuss. Kreiss-Physikus," gives an account of the necropsy. The liver was so friable that it broke on pressure. The much enlarged gall-bladder contained a slimy fluid instead of bile, and 25 gall-stones of various sizes. The largest stone was impacted in the common bile-duct so as almost to prevent the passage of a bristle. The spleen was much enlarged and fell to pieces on palpation. A small collection of pus was found in the right kidney. The chest contained two "stof," or about 2400 c.c. of water. The left side of the heart was small and contained many polypi. The right side of the heart was much enlarged, and the aortic valve much ossified. The report of the necropsy concludes with the remark that no medical skill could have saved the patient. Probably the state of the liver and spleen was largely due to post-mortem changes, as the necropsy must have been performed a considerable time after death. Dr. Bertels thinks that the "polypi" in the left heart

were nothing but blood clots, and that the "abscess" in the kidney must have been a small fibroma, hypernephroma, or adenoma—tumours which are often found in the kidneys in the course of a necropsy. It is certainly conceivable that the pain in the chest may have been due to biliary colic, for it is now known that an impacted gall-stone may cause pain referred to the chest and not to the gall-bladder or bile-ducts. But it is doubtful whether the conditions observed in the abdomen can alone account for the patient's death. It is true that gall-stones may prove fatal when peritonitis, cholæmia, or cholangitis supervenes. The two former may be excluded, for the report of the necropsy says nothing of peritonitis or jaundice, the absence of which suggests that the impacted stone cannot have completely obstructed the flow of bile. It is possible that cholangitis may have been present, but overlooked owing to the considerable interval between death and the necropsy. Yet Dr. Bertels regards this explanation as unconvincing; and he is inclined to trace the pain in the chest and the patient's death to sclerosis of the coronary arteries of the heart. These were apparently not examined after death. The facts that Barclay de Tolly continued his journey in a carriage till a few hours before death and that there was no record of fever suggest that death was due rather to heart disease than to cholangitis. The hydrothorax was probably the outcome of cardiac weakness during the last hours of life rather than of pleurisy or a chronic stasis. Thorough as is the report of the necropsy, this case illustrates in a striking manner the advances made during the last 100 years in our knowledge of morbid anatomy.

AN OPEN SAFETY-PIN FOR TEN DAYS IN THE ŒSOPHAGUS OF A BABY.

IN the *South African Medical Record* of Oct. 11th Dr. T. G. Blackburn has reported a remarkable case in which an open safety-pin remained for ten days in the œsophagus of a baby aged 3 months without producing any symptoms. The child was admitted into the Provincial Hospital, Port Elizabeth, with the history that she had swallowed a safety-pin. There were absolutely no symptoms; she was bright, happy, and laughing, and took the breast as usual. On the next day a radiogram was taken and clearly showed the pin fixed in the œsophagus, open, with the point upwards, about opposite the middle of the sternum. Interference was considered dangerous. Extraction upwards could be performed only if the point could be grasped and so prevented from doing irreparable harm to the œsophagus—a feat of manipulation practically impossible in such a narrow space. Trying to dislodge the pin had also its dangers, because if the bougie passed beyond without dislodging, on withdrawal it might drive the point into the œsophageal wall. Taking all the points into consideration, as well as the fact that the child was suffering no inconvenience, it was decided to wait, carefully watching the condition daily on the fluorescent screen. A week after admission the child first showed symptoms. She had crying bouts and was more restless, though there was no rise of temperature or vomiting. This condition continued for three days, and as the pain was thought to be due to commencing ulceration of the œsophagus it was decided that something must be done. She was placed on the X ray couch with the tube underneath and the fluorescent screen on top. A metal bougie large enough to fit the œsophagus was then passed till it was seen to touch the blunt arm of the pin. On applying slight pressure the pin was dislodged and passed down behind the cardiac shadow and appeared in the stomach. The pin was now in an accessible position, but it was decided to give Nature another chance and to see whether the pin would turn shut end down and be passed per vias naturales. Two days later it was seen to be fixed at the pylorus open end down. As nothing further was to be gained by waiting, the stomach was opened through a median incision made just below the xiphoid cartilage. The stomach and pin were brought to the incision. A slight incision over the blunt end allowed easy extraction. Three fine sero-muscular sutures closed the stomach opening and purse-string suture around this was used for security. The child stood the operation well and six hours afterwards took the breast. Recovery was uneventful.

THE EXPECTATION OF LIFE IN ANCIENT ROME.

THE study of the classics has during the last 30 years developed from what may be called a purely literary investigation—i.e., questions of text, grammar, and style—into the study of social and human problems. Thanks to the labours of scholars such as Dill, Glover, and William Arnold the society of the Empire is brought before us as a living society, and as one which only too closely in some ways resembles our own to-day. Mr. Raper, in the *Classical Review* for February, 1913, evolved an ingenious and charming theory about Vergil as a priest of Apollo (with a possible strain of Jewish blood), and a descendant of that Thracian Maron who provided Odysseus with the potent wine by means of which he subdued the Cyclops; while Mr. Mackail, in the current *Journal of Roman Studies*, has shown in his own brilliant manner the close connexion between Vergil and Roman studies, his accurate archæology, his advocacy of "small holdings," and his treatment of other economic problems. The weariness of life in a great city, the crowds, the dirt, the struggles of those who really were in "the smart set" to maintain their position, and of those who were not yet numbered in that blissful company to attain to it, are contrasted with the peaceful life of the country both by Vergil in his gentle, saintly manner and by Juvenal in a style very much the reverse. Confirmation of the unhealthiness of life in ancient Rome is afforded by a study of the Latin inscriptions, and such study has given birth to a most interesting paper by Dr. W. R. Macdonell which appears in *Biometrika* for October. Dr. Macdonell searched those portions of the Corpus Inscriptionum Latinarum which refer to Rome, Hispania, Lusitania, and Africa respectively. The Roman inscriptions he divided into two classes—namely, the civil population and the soldiers in garrison. As regards the former, Dr. Macdonell gives curves comparing their expectation of life, so far as it can be calculated from ages at death, with the curves shown in the Registrar-General's report for 1891–1900. The difference between the modern curve and that of Rome is enormous at first, while the Roman curves for both sexes are practically level for the first 40 years of life. For this period the Roman's expectation of life was roughly 23 years, while the English curve shows at birth an expectation of about 57 years, at 20 years of age an expectation of 40, while

between 50 and 60 years the modern and ancient expectations coincide. After 60 the ancient expectation is better than the modern, which Dr. Macdonell accounts for by the selection of the young, which is obvious from the heavy mortality among them. As to soldiers in garrison, curves could not be plotted for lack of material, but the inscriptions show that their expectation of life was inferior to Roman males, and between 25 and 50 years to Roman married women. When the figures for Hispania and Lusitania are taken, the expectation of life in childhood rises at once, while two deaths are noted at the age of 115 and one at the age of 125. For the first 30 years of life provincial expectation is far higher than in Rome. It decreases until 45, and from 45 to 75 is about the same. As regards the province of Africa expectation of life was fairly comparable, if somewhat lower, with the English curve up to 40; after that age it was superior. As regards Rome it was superior at all ages. It is worth noting that "senectus" was considered by the ancients, notably Cicero in his "De Senectute," to begin about the forty-sixth year of life.

RECURRENT INTUSSUSCEPTION AFTER OPERATION.

RECURRENCE of intussusception after operation has rarely been observed. In *Guy's Hospital Gazette* recently Mr. Edward M. Mahon reported the following case. A boy, aged 3 years, was admitted on July 15th, 1913, for abdominal pain, vomiting, and the passage of blood per rectum. In November, 1910, he had been admitted with the same symptoms. Intussusception was diagnosed, and Mr. C. H. Fagge operated and found the ileum intussuscepted into the ileum and thence through the ileo-cæcal valve into the colon. On reduction the gut was found to be very black, and it was doubted whether it was remediable. The intussusception was said to be of 11 hours' standing. The history of the present attack was that the patient had been perfectly well since the first intussusception until the day of admission. At 9.30 A.M. a sudden paroxysm of abdominal pain occurred. It lasted about four minutes and caused him to fall to the floor. Vomiting accompanied the pain. After the attack he felt quite well again, but during the next eight hours about 24 similar attacks occurred. At 2.15 P.M. tenesmus accompanied a paroxysm of pain, and blood was passed. With every subsequent paroxysm there were tenesmus and passage of blood. Eight hours after the first attack he was admitted. The abdomen was quite soft and moved well on respiration, but there was some tenderness beneath the right costal cartilages. At first nothing could be felt in the abdomen, but during a palpation a sausage-shaped lump appeared below the right costal margin and disappeared. On rectal examination nothing abnormal could be felt, but on withdrawing the finger it was found covered with blood. Intussusception was diagnosed. Mr. E. C. Hughes operated 11¾ hours after the onset of symptoms. Under the anæsthetic a distinct mass was felt below the right costal cartilages. The abdomen was opened through a rectus incision and the cæcum was found missing from the right iliac fossa. There was a mass high in the right hypochondrium. This proved to be large intestine with the ileum passing into it, and appeared to contain ileum, cæcum, appendix, and ascending colon. Reduction was easy, the colon first appearing, then the appendix, cæcum, and ileum. The last part of the reduction was ileum from ileum. The intussusception began two inches from the end of the ileum. Nothing was found to account for its origin. Rapid and uneventful recovery ensued. Only six cases of recurrence of intussusception in children after reduction by laparotomy appear to have been recorded. Mr. Charles P. B. Clubbe, in his "Diagnosis and Treatment of Intussusception," writes: "A recurrence following supposed complete reduction by injection or inflation does occur and must always be expected. But a recurrent invagination coming on immediately or soon after reduction has been effected by laparotomy is very rare. It did not occur in any of my cases. I have operated on two children for recurrence of intussusception coming on two and six months after operation." Mr. Clubbe's series consisted of 144 cases, and extended over a period of 13 years. Messrs. Adams and Cassidy in "Acute Abdominal Diseases" record only one recurrence in 100 cases, and this occurred five weeks after operation. Mr. D'Arcy Power in "Some Points in the Anatomy, Pathology, and Surgery of Intussusception" writes: "An intussusception sometimes recurs after it has been reduced by abdominal section, but recurrence is less usual after an abdominal section has been done than when reduction has been brought about by irrigation. In a few cases the intestine has remained so œdematous that the tumour has been felt after the wound has been closed, leading the operator to suppose that invagination has recurred. Such a condition may be distinguished from true recurrence by the fact that the swelling rapidly disappears, and with it the symptoms of obstruction. This is a rare accident, but Sir A. Pearce Gould met with a rarer one in which he performed laparotomy twice at an interval of three months for the reduction of two separate intussusceptions in the same patient." In the "Index Catalogue of the Library of the Surgeon-General's Office" are two references to recurrence of intussusception after operation, the intervals being 3½ months and five weeks respectively.

KING EDWARD'S HOSPITAL FUND FOR LONDON: ST. GEORGE'S HOSPITAL AND THE DISTRIBUTION COMMITTEE.

THE Governors and General Council of this Fund held a meeting on Friday morning, Dec. 12th, in St. James's Palace, the Duke of Teck presiding, at which the splendid financial position of the Fund was well revealed. Lord Rothschild, the honorary treasurer, reported that the amount received by the Fund up to Dec. 6th, after payment of expenses, was £150,000, while the fund had a sum of £170,000 on deposit with Messrs. Baring Brothers. He informed the governors that under the will of the late Sir Julius Wernher, by which the fund received one-twelfth of the residuary estate, a sum in all of £465,000 would shortly be received. £151,000 were placed in the hands of the committee for distribution among applying charities, and the details of the awards to the various hospitals, which have been published in the press, show great care in consideration of the various facts that dictated the awards, while the distribution committee are careful to draw attention to the fact that absence of a grant does not necessarily imply dissatisfaction with the charity. The committee report that the authorities of St. George's Hospital have now rendered their accounts for the year 1912 in an

amended form, reducing "the amount paid to the medical school out of the general fund of the hospital, in respect of specific work done for the patients, to a sum not exceeding that which was charged prior to the changes which led to the suspension of the Fund's grants." The committee therefore recommend a grant of £3000 to the hospital "subject to a certificate from the chairman of the hospital that the accounts for 1913 will be in conformity with those now presented for 1912." The Mount Vernon Hospital for Consumption does not now appear in the list since the hospital at Hampstead has not applied for a grant, and that at Northwood, being no longer a branch of any hospital applying for a grant, has been regarded as outside the area to be dealt with.

EARLY OPERATION IN CASES OF APPENDICITIS.

OUR Swiss Correspondent writes: "At the request of the newly founded Swiss Surgical Society Professor F. de Quervain, of Basle, collected several thousand reports on cases of appendicitis operated on in the years 1908 to 1912. As Switzerland still loses 400 of its inhabitants yearly from appendicitis, this collective report, published in the *Korrespondenzblatt für Schweizer Aerzte* on Dec. 6th, deserves attention. In Professor Sahli's Bernese statistics of 1895 still 21 per cent. of all the operation cases died; the total mortality, however, was only 9·6 per cent. This referred to 7213 cases. Professor de Quervain finds for his 6116 cases the operation mortality was reduced to 8·1 per cent., the total mortality having sunk to 7·8 per cent. In 404 operation cases at the Basle clinique from 1910 to 1912 the mortality was reduced to 6·2 per cent., the total mortality being 5·7 per cent. This was principally due to the fact that 164 cases could be operated on the first day, 104 cases on the second day. How much depends on early operation the following data prove:—

	Cases.	Mortality.
Operation on first day	1723 ...	0·7 per cent.
,, second day ...	1389 ...	4·7 ,,
,, third ,, ...	788 ...	10·7 ,,
,, fourth ,, ...	1197 ...	21·2 ,,

The length of stay at the hospital increased according to the later date of operation from 17 (first day) to 21, 31, and 40 days (for the fourth day). At the Bernese clinique only 6 patients succumbed out of 299 acute cases undergoing operation, and these had only entered after the fourth day. All the cases undergoing operation on the first and second days of the attack were cured."

PELLAGRA IN IRELAND.

WE publish in another column a further contribution to the study of pellagra in the United Kingdom. The case which Dr. F. E. Rainsford reports from the Stewart Institution at Chapelizod, co. Dublin, seems to have been a characteristic instance of the disease, pursuing, moreover, as has so frequently happened with the earlier cases of an advancing disease, a comparatively acute course and ending in death. The description of the symmetrical dermatitis, the gastro-intestinal symptoms, and the nervous symptoms can leave no doubt as to the accuracy of the diagnosis. In this case, further, as in the majority of the English cases hitherto reported, the patient was the inmate of an asylum, to which she had been admitted before any somatic symptoms made their appearance. It cannot be said that the mental features of the case presented any unusual or exceptional element; and the circumstances, therefore, do not support the view of the mental symptoms of pellagra being in any way pathognomonic. Dr. Rainsford does not mention if any necropsy was conducted, and further details as to the previous environment and mode of living of the patient would add in interesting manner to the contribution. We are glad to think that the case has not been missed, that several physicians concurred in its diagnosis, and that it has duly been recorded in medical literature. In this way interest is certain to augment, and both the medical profession and the public whom they serve will ultimately reap the benefit of increased knowledge and hopefulness in treatment.

AMBULANCE SERVICE FOR THE METROPOLIS.

IN regard to the scheme prepared by the Metropolitan Asylums Board, at the request of the London County Council, for the provision of a street ambulance service for the metropolis, the General Purposes Committee reported to the Council on Dec 16th that it could not recommend the adoption of the scheme on the grounds that it was not in accordance with the Metropolitan Ambulances Act of 1909 and that it was proposed that the administration should be wholly in the hands of the Asylums Board while the Council bore the cost. There was no precedent for the delegation by the Council of its powers in such a way. As the Board had no power to incur any expenditure in the matter the Council would have to reimburse, whether it approved the expenditure or not. The committee had come to the conclusion that the organisation and provision of an efficient system must rest with the Council. A certain number of authorities had ambulances which would be placed at the service of the Council, but these were insufficient, and additional provision must be made. During the meeting of the Council on Dec. 16th a report was circulated containing the proposals of the committee. The report was of an entirely tentative character, and indicated the intentions of the committee to establish ambulance stations with motor ambulances in six outlying districts, with one station in central London. It was thought that the service might be carried on under the supervision of the chief officer of the Fire Brigade. In addition to motor ambulances the committee proposed to provide hand ambulances or litters for carrying injured persons for short distances. The committee hoped after the Christmas recess to submit a detailed scheme, with estimates of cost.

THE RUMPEL-LEEDE PHENOMENON IN SCARLET FEVER.

NEARLY three years have elapsed since Rumpel and Leede first described in the pages of the *Münchener Medicinische Wochenschrift* a peculiar phenomenon in patients suffering from scarlet fever, which they suggested might supply a test for the diagnosis of this disease; yet so far as articles in our medical journals are an index little notice seems to have been taken of their work in this country. At last, in the current number of the *Edinburgh Medical Journal*, there is published a paper dealing with this phenomenon, written by

Dr. George Richardson and setting forth his experience of it as a diagnostic measure. Briefly stated, the phenomenon consists in the appearance of subcutaneous petechial hæmorrhages on the forearm of patients suffering from scarlet fever, when a bandage is applied just above the elbow sufficiently tightly to constrict the veins while allowing the arterial circulation to continue somewhat feebly, the pulse at the wrist being just perceptible. The hæmorrhages appear during the reaction when the bandage is removed, some degree of "capillary vulnerability" being apparently produced by the toxins of the disease. Dr. Richardson finds that the reaction is invariably obtainable in scarlet fever patients up to the end of the fourth week, and if complications are present up to the end of the fifth, though difficulties may be met with in producing it in infants with soft, fat arms. No hæmorrhages are producible by this procedure in cases of acute specific fevers in which there is no eruption, such as diphtheria and whooping-cough, but in patients in whom the rashes of measles or rubella are visible, or even in cases of drug eruptions and serum rashes, a somewhat similar phenomenon may occur. It fails, however, as soon as the rash in question has disappeared. It seems, then, that the test is of considerable value as a means of recognising scarlet fever at stages of the disease in which the rash has faded, but that it does not serve to differentiate between the rash of this disease and an erythema occurring in other conditions until the actual cutaneous disturbance has subsided. The procedure is so simple that it certainly seems worth while, for those who have the opportunity, to make further investigations as to its accuracy as a diagnostic measure, as cases are not rare in which recognition of an attack of scarlet fever in the post-eruptive stage is both important and difficult.

FOOD ADULTERATION AND CHRISTMAS FARE.

SPECULATIONS have appeared in certain lay papers as to the probability of the stock fare of the season showing on examination systematic adulteration. Exaggerated statements in regard to this matter have been made. It would be absurd, of course, to give an absolute undertaking that all the food partaken of this Christmas will satisfactorily pass the portals of analysis, but it would be fairly safe to anticipate that an examination would disclose the practical absence of objectionable ingredients. That is to say, if there were found any adulteration at all it would not be of a very serious kind, or exist to a serious extent. After all, it is to be remembered that the present Sale of Food and Drugs Act, though it has certain defects, works very well in the direction of protecting the consumer, and the figures of the past 10 years show a gradual fall in the percentage of adulterated samples. Whatever may be said in regard to the desirability of introducing reforms in this department of State health administration, the fact remains that our food supplies at the present moment are very carefully watched, and it is doubtful, speaking generally, whether a higher standard of purity has ever been reached or maintained before. Modern offences are mostly petty in kind, amounting here and there to the presence of a small quantity of preservative which in a good many instances proves to be unobjectionable, or, again, to a deficiency of cream in milk, or to a foreign but innocuous colouring matter in sugar. The fraud committed through trading in food commodities is not so rife as it used to be, while the use of poisonous materials has practically been stamped out. So long, therefore, as the officials responsible for the working of our Food Acts do not relax their admirable energies we may reasonably hope that the present good general standard of purity in regard to food-supplies will not be lowered, because of the extensive buying of the Christmas season. It should be added that to submit the staple fare of Christmas to chemical analysis might be waste of time. It is not always that analysis can be trusted to give an explanation of disagreeable symptoms when they happen to arise. Modern instances of food poisoning rarely furnish a clue to the chemist or analyst. The contamination is nearly always biological and therefore a matter for the bacteriologist and pathologist to clear up. The safeguard is to keep food-supplies in clean surroundings.

THE MESOTHORIUM TREATMENT OF CANCER.

AT the German Congress of Gynæcology Professor Krönig, of Freiburg, and Professor Gauss reported that they had devised a new method of giving large doses of mesothorium; it consisted in the use of a special filter for the rays, so that the alpha and beta rays which have a severe burning effect were completely absorbed by the filter and the gamma rays alone remained. The filter employed consisted of a layer of lead two millimetres thick, a layer of gold three-quarters of a millimetre thick, and a layer of platinum half a millimetre thick. Previously they had treated 26 patients with unfiltered mesothorium rays, and in every case recurrence had occurred, ending in death. They had also treated 64 cases with mesothorium rays and with X rays in order to avoid recurrence after removal of the growth by operation. These 64 cases were divided into two groups. In the first group of 43 cases the X rays were for the most part unfiltered, and of these cases 23 have since died with recurrence of the growth. In the remaining 21 cases in which all the rays were filtered no recurrences had occurred at the time of the communication. They had also treated 48 cases of inoperable cancer by the new method, and of these 18 were still under treatment. Of the remaining cases 17 might be claimed as completely cured, for in several of them local excision and histological examination had shown that the disease has been completely removed and that no recurrence had taken place. In 5 cases death occurred during the treatment. In 8 cases the treatment was discontinued at the request of the patients. The longest interval of freedom from relapse had been a year and two months. The cases included examples of cancer of the uterus, the breast, the œsophagus, the face, and the stomach. They had come to the conclusion that large doses of mesothorium and X rays, if injury to the skin is avoided by filtration of the rays, have a curative action on the cancer cells even in the deeper layers, though there is no effect on metastases. Professor Döderlein, of Munich, confirmed the statements of the authors of the paper; he said that he had ascertained by means of excisions the gradual destruction of the cancer cells in the various stages of the treatment until they disappeared completely. The malignant tissue was replaced by a mass of firm fibrous tissue, the

discharge and hæmorrhage disappeared, and the general state of the patient improved.

VITAL STATISTICS FOR 1910 OF THE UNITED STATES OF AMERICA.

WE have received from the Census Bureau at Washington a report on the mortality of the Registration Area of the United States for the year 1910. This report, which is the eleventh of the series, appears as a folio volume of more than 600 pages, and is the work of Dr. Cressy Wilbur, chief statistician of the Census Bureau. The population whose mortality statistics are now published amounts to 58·3 per cent. of the entire American Republic. The territory thus inhabited, and designated the Registration Area, occupies fully one-third part of the vast domain of the United States. In a preface Dr. Wilbur intimates that, although the mortality records now presented are directly comparable with the population statistics as enumerated at the thirteenth Census, full details respecting the latter are not yet available. Consequently, the general or crude death-rates alone can now be given. Nevertheless, complete details of mortality, derived from comparison of deaths with population, by means of corrected death-rates and life tables, together with an analysis of occupational mortality, are promised in a forthcoming volume, the preparation of which has already been commenced. Accordingly, the present volume must be regarded as a continuation of the series of annual reports already published, which deal generally with the mortality of various parts of the country. By means of tables in the text, which are comparable with those published by the English Registrar-General, the general tendency of mortality from all causes and from specified causes may be studied and comparison readily made with changes in foreign countries. From one of these tables, relating to 1910, it appears that the crude death-rate of the entire Registration Area was 15·0 per 1000 living, against 13·5 per 1000 in England and Wales. It was somewhat higher than the rates of 1908 and 1909, but with these exceptions was lower than in any previous year respecting which statistics are extant. The present report, which has apparently been compiled with great care, marks a distinct advance in American vital statistics, and under the able direction of Dr. Wilbur still further improvement in this important direction may confidently be looked for in the future.

THE proposed amalgamation of St. George's Hospital and Westminster Hospital is now in jeopardy owing to a difference of opinion which has arisen on the question of a common site, and a meeting of governors of St. George's Hospital will consider a proposal made by their house committee for sanction of the purchase of a site at Wandsworth.

Sir Alfred Pearce Gould has sent to Prince Alexander of Teck, as chairman of the Middlesex Hospital, £1000 which he received from "a friend," for the purchase of radium to be used in the treatment of the patients in the cancer wards of the hospital.

THE London Post-Graduate Association, we are informed by the secretary, is to be wound up at the end of the year.

THE INDIAN MEDICAL SERVICE.

THE Public Services Commission took up the inquiry into the Medical Services on Nov. 21st.

Surgeon-General Sir C. Pardey Lukis, Director-General of the Indian Medical Service, who was first examined, expressed no views regarding probation and training, as the present system, he thought, was quite good. Out of the sanctioned strength of 748 officers in the Indian Medical Service, only 722 posts had been filled up, of which 54 were Indians. Out of these 54, only 28 applied for civil employ. Before long they would have the station hospital system for Indian troops on the same lines as for British troops. In his opinion it did a man no harm in being put to regimental duties for six years. He thought all Indian Medical Service officers should be placed on the general list as regards selection for the grades of lieutenant-colonel, adding that there was no doubt that the best men were not coming into the service. "The reason for this," said Sir Pardey Lukis, "is that an impression has got abroad that the Indian Medical Service is going to be broken up. I am not saying it as my own impression, but it is an impression at home." He gave figures to show that the number of Indians in the service of late years had increased considerably. Out of 72 new appointments 15 were Indians. He hoped the training of candidates would be augmented by a course of study at the new Tropical Diseases School in Calcutta. In his opinion the training was satisfactory. He had been much astonished at the figures which showed the number of applications from candidates to enter the civil service. The figures were 52 per cent. Indians and 87 per cent. of Europeans. He would have thought that they would have been the other way round. In the cases of men who were to enter the civil service, witness did not think that service with the regiment should be too long. All appointments for ordinary civil work were made by seniority without regard to the question of military rank, and, in his opinion, any system of selection would be injurious. The witness said that at present 331 out of 475 of civil surgeons were under orders for reversion to military duties in the event of a general mobilisation. The number of men who sought service in the Indian Medical Service had decreased. Young men were, in fact, so fully occupied now in England that a practitioner would have to pay 8 guineas a week for a locum tenens instead of the 2 guineas which was paid a few years ago. "We should be depending on a broken reed," said the witness, "if we relied upon England and the colonies in the event of mobilisation. Here, so far as we can ascertain, there are 1771 independent practitioners holding qualifications, Europeans and Indians. The Europeans are under contract with big firms and their services would not be available even if they were willing to come. Many of the Indian practitioners have large practices in big cities, and I cannot think they would give these up. Many of the remaining men belong to the non-martial races, so would not be the kind of men we should desire. Some time ago we tried to find out the number of practitioners who would volunteer. We found 24, all Europeans, and these facts," added the witness, "justify me in holding the opinion that the question of the war establishment is one of considerable importance."

The standard of training in the Indian medical institutions at Calcutta, Madras, Bombay, Lahore, and Lucknow, Sir Pardey Lukis thought, was good, and in some cases better than that given at home. The only defects were the non-insistence on practical training for students before granting them diplomas, the understaffing of colleges, and the want of development in special branches of study, such as throat and ear diseases. All examining bodies at home insisted that students should have attended confinement cases before they qualified themselves, which owing to existing conditions in India was not possible: for the M.B. examination in the Punjab University, a registrable qualification, students were not required to have practical training regarding women's diseases. The M.B. of the Punjab University could go direct to the Indian Medical Service, and though he could get into the service he was not qualified. Therefore witness laid stress on the importance of insisting that students should undergo practical instruction in women's and children's diseases. He suggested that the marks should be raised from 600 to 700 in women's and children's diseases as in medicine and surgery.

Sir Pardey Lukis next said that civil assistant surgeons had a better training than military, and that the former's were registrable qualifications. He suggested that students in the military assistant surgeon's grade should have the same training as those in civil employ. He submitted in January, 1911, to the Government of India a letter suggesting this improvement, and a dispatch had been sent home. The only advantage the military assistants had was that after passing the examination they went with British troops and obtained an excellent training, not only with soldiers, but with women and children; and in the treatment of women and children they were better than the civil assistant surgeons. Military assistant surgeons had training in X ray work and bacteriology, but he would like to see them from the very beginning receiving the same training as civil assistant surgeons. The defect in their training had an effect on their popularity. The witness said, in reply to Lord Islington, that there was no medical college entirely devoted to women in India, and this had generally an effect in keeping away the better class of Indian women from taking to medicine. When Lady Hardinge's Medical College for Indian Women at Delhi was opened he hoped a better class of women would join it. The scheme was complete and the names of the selected students would be announced as soon as Her Excellency returned to Delhi. There were 355 medical missionaries in India and they were serious rivals not only to the civil surgeons but to independent practitioners also, as missionaries treated practically for nothing in return. To stop medical practitioners who had no qualification from practice a Bill was passed by the Bombay Legislative Council in March, 1912. A similar Bill introduced in the Madras Council by the Hon. Dr. T. M. Nair, was under consideration, and one would be brought before the Bengal Council during the ensuing winter. An Imperial Act was also under consideration. But those Acts were not intended to interfere with the practice of the Eastern system of medicine.

There were only two places in India—Calcutta and Bombay—where independent medical colleges could be established. He gave an account of the private medical institutions in Calcutta. The hospital at Belgachia, in connexion with the Albert Victor Hospital, was an excellent institution with a good surgical and medical staff, but was badly handicapped for want of funds, and consequently for the necessary building and equipment. He had heard unofficially that the Bengal Government had decided to give 5 lakhs non-recurring and 50,000 a year recurring for the upkeep of this institution on condition that the college was affiliated to Calcutta University and the necessary building and equipment for a hospital were provided. This, Surgeon-General Lukis thought, would form a great outlet for independent medical practitioners.

Replying to questions concerning the unpopularity of the Indian Medical Service with young men at home, Sir Pardey Lukis said: Personally, I believe that the Indian Medical Service is now as safe as it ever was and that it presents as many opportunities for good careers as ever. I have been preaching that gospel for some little time, and I was horrified to find how little impression I could make.

Mr. Ramsay Macdonald: Is the unpopularity of the service due to the assumption that the enrolment is not good or that the service itself is going to suffer at some future time?

Sir Pardey Lukis: The whole of this trouble has arisen since Lord Morley's circular. The unpopularity of the service was due to the fear that one-third of the civil surgeoncies would be given over to independent medical men, and to military surgeons being absorbed by the Royal Army Medical Corps.

Replying to Mr. Madge, Sir Pardey Lukis doubted whether the Director-General should be joint secretary in the Home Department.

In reply to Mr. Abdul Rahim, Sir Pardey Lukis said that the cause of the unpopularity of the service was the insufficiency of the salary given to members and the employment of independent medical men in responsible posts.

In examination by Mr. Gokhale, Sir Pardey Lukis said that in the event of civil surgeons reverting to military duty in times of war the positions thus made temporarily vacant would be filled by the assistant surgeons. The number of men liable for military service would cause a big dislocation, but they would not all be recalled at once, but in six different sections. If the whole of the Indian army was mobilised a large number of civil institutions would have to shut up.

Replying to further questions, Sir Pardey Lukis said that in England a young practitioner after graduating went to quiet places and then went into big towns, but a young Indian would not do that. He was not aware of an impression among Indian members of the Indian Medical Service that only inferior posts were given to them; such an impression was not justified. 75 per cent. of the European members of the service possessed the higher qualifications, and 153 officers of the service had specialised themselves. He did not approve of the appointment of independent medical practitioners as professors in Government colleges, but suggested the establishment of private institutions where the abilities of such men could be utilised. As to the desirability of appointing Indian assistants to posts when vacancies occurred in the department in which they had served for a number of years, Sir Pardey Lukis said that Indian assistants had done well. In Calcutta Rai Bahadur Chunilal Bose had officiated at various times. Sir Pardey Lukis added that the defects pointed out in the Punjab University examination in his opinion existed in other places too.

In reply to Mr. Sly, he said he would have no objection to Indians being given a scholarship to proceed to England for medical tuition after they had obtained their diploma. He would accept a scheme of study leave, applicable to military assistant surgeons, civil surgeons, and Indian Medical Service officers.

Mr. Fisher: Considering the formidable list of duties which a civil surgeon has to do, would you be in favour of specialisation?

Witness: I am quite in favour of the amalgamation of the sanitary with the bacteriological department, provided the Director-General of the Indian Medical Service was head of their department with the Sanitary Commissioner as his staff officer.

Answering Sir Valentine Chirol, witness said that in view of the fact that personal claims must be subordinated to the Indian Medical Service which was essentially a military body, it was not hard to understand that no Indians volunteered for war service. Also it must be remembered that of the total number of independent practitioners nearly 1000 Indians belonged to non-martial races. In order to bring India up to the numerical standard of practitioners in Great Britain there would be required a total of 250,000 practitioners.

To Sir Murray Hammick, Sir Pardey Lukis said that there was no difference in the scale of pensions given to military men and civil employes of the service, and there should be the same *cadre* in the provinces all over, so that efficient men could be imported from outside when necessary without difficulty.

The second witness, Major R. F. Baird, I.M.S., civil surgeon of Benares, who represented the United Provinces, said that the main causes of uncertainty regarding the service was the possibility of a rush of private practitioners and a suggestion that a good number of civil work would be handed over to them. He considered that the medical training obtained at home was superior to that given in India, and recalled the fact that the Indian University qualified men had to undergo training in England before they could get into the service. In India the training was defective, especially in midwifery and children's diseases. He advocated, among other things, the giving of house surgeoncies in big hospitals to private practitioners, and said that if a civil surgeon had an extended private practice it increased his efficiency, while during the military period of an Indian Medical Service officer's career he gained no teaching experience. He advanced no objection to professorships being given in the colleges to independent practitioners. It was urged that civil surgeoncies should be held by Europeans, because they had practice among European families. He admitted that that argument could cut both ways; but in the cases of Indian ladies it did not apply so strongly as they would not see any man at all.

Mr. Gokhale having interposed the remark that the *purdah* system was not so strong in other parts of the country as in the United Provinces,

Captain J. T. Parkinson, I.S.M.D., said that he represented 53 surgeons of the United Provinces of the Indian Subordinate Medical Department. He said that it seemed

anomalous to him that his department was called subordinate.

Mr. U. N. Bannerjee, representing the assistant surgeons of the United Provinces, said that his colleagues complained of the scale of pay and the exclusion from higher appointments.

Dr. Bhawat Ram Sawhney (representing the Punjab Medical Union) was the first witness taken on the second day of sitting. He agreed that no Indian should enter the Indian Medical Service without holding British qualifications. He urged the recruitment in England of a staff of professors for medical colleges in India. He was not in favour of Indian Medical Service officers taking professorial work, believing that deterioration in efficiency of medical practice was due to entrusting work to Indian Medical Service officers who had no experience of that work. In teaching hard work was required and great interest should be evinced. Indian Medical Service officers with the necessary training, qualifications, and ability made good professors, but he was of opinion that they lost freshness and did not obtain after coming out to India the experience essential for teaching. He urged the reduction of the present medical organisation by half and the substitution of private practitioners. He thought that private practitioners could be encouraged without the adoption of any change so sweeping as to have serious effect on the Indian Medical Service. He remarked that London hospitals were closing their doors against the Indian student, but better understanding would change that attitude. It was advisable for Indians to study in India, but he would have all full surgeons trained in England. He added that his experience of training colleges in India was gained 35 years ago, and improvements must have been made since then. He knew, for example, that the professors now went on study leave.

Lieutenant-Colonel H. Smith, civil surgeon, Amritsar, thought that Lord Morley's circular had still influence in the service. There was a feeling of uncertainty about the future. He would make all Indian candidates go to England. If they did so it would be to their advantage. They would be placed on a similar footing to that of Europeans. He thought the standard of Indian colleges was "up to the times," and there was not the social life and rough-and-tumble of an English college. He would restrict the number of Indians who desired to enter the service to 20 per cent. "The medical practice in the Punjab," continued witness, "is as overstocked as is the Punjab Bar." Most Indians, witness continued, had agreed to leave nominations to the Indian Medical Service with the Government, and that the number of Indians in the service should be restricted to a maximum of 20 per cent. He said that the scope for corruption and bribery open to a civil surgeon engaged in legal work was enormous, and that, as English practitioners understood it, there was no such thing as professional etiquette in certain classes of practitioners in India.

Lieutenant J. F. Fleming, Deputy Superintendent of Lunatic Asylums in Lahore, stated that though the subordinate department were entitled to a month's privilege leave in the year, they were not given that, and they had no holiday in the year, not even on Sundays or public holidays. He objected to the placing of their department on an equality with civil assistant surgeons. Without making any suggestion as to the limitation of Indians in the Indian Medical Department, he was of opinion that Europeans wielded greater influence and commanded more respect from the people.

Mr. Mirza Yaqub Beg, civil assistant surgeon, Punjab, suggested the creation of more posts for civil surgeons, so that officers with the necessary qualifications of civil assistant surgeons might have a reasonable chance of holding higher appointments. He stated that in view of the hard work and incessant travelling civil surgeoncies should be given to the younger members of the department. Civil assistant surgeons in his province claimed exemption from the provisions of the Arms Act. That was a privilege they should be entitled to in view of the number of dacoities and other outrages that were committed in parts of the Punjab. The conditions of salary and pension were matters of complaint. Their pay was not adequate considering their arduous duties. Witness advocated retirement on pension after 20 years' service on the ground that the service was hard-worked.

Assistant Surgeon J. Malir, speaking for the I.S.M.D. Railway Sections, was the first witness on the third day of sitting. He stated that assistant surgeons of railways demanded, *inter alia*, the same privileges as were granted to the Indian Medical Service. They performed the same duties as civil surgeons, and it was only in exceptional cases that the aid of civil surgeons was requisitioned, and then only for consultation. He knew many cases where military assistant surgeons were serving under civil assistant surgeons, and he saw no objection to it. As regards the comparative training of civil assistant and military assistant surgeons, the superiority of the former existed in theory only. In practice the military had more outdoor work to do and they gathered more practical experience.

Major R. M. Dalziel, I.M.S., superintendent, Central Jail, Punjab, said that the jail service was not popular, and difficulty was experienced in getting officers to enter the branch. Indian medical officers had conducted the jails so well in previous years that he could not see the need for any change. He was not in favour of transferring superintendents from one province to another on promotion; but he advocated promotion in the same province to the Inspector-Generalship. He was of opinion that by inter-provincial transfers there was a likelihood of interference with seniority claims of other officers, so that in one province an inspector-general might be senior to the next man by a few months. The central jails in big cities gave a good scope for the training of superintendents. He did not agree that assistant surgeons should take charge of jails. He did not think there would be any advantage in appointing a separate medical officer in addition to the superintendent who could give an opinion on the prisoners' health. He also did not agree that the governorship and surgeoncy of a jail should be held by different men.

Lieutenant-Colonel Browning-Smith, I.M.S., Sanitary Commissioner, Punjab, said that for the sanitary department of the Indian Medical Service officers drawn from the military were better than those in civil employ. A medical officer of a regiment had heavy work to do as to sanitation of troops. He thought many Indians particularly fitted for sanitary work in view of their knowledge of public health and their acquaintance with the language and customs of the people; on plague duty they had been of very great use to him. He had two deputy sanitary commissioners, one of whom was an Indian. He suggested that promotion in the sanitary department should be from one list for all India. The language problem certainly presented a difficulty, but he did not think it was insurmountable. In the sanitary department a European officer would have more authority with the people than would an Indian private practitioner. The Punjab Municipal Act gave large powers to sanitary officers, but it was a dead letter, and to that, and because they were not yet educated up to it, was due the apathy of local bodies. He quite saw the advantage of women doctors in sanitary work, but he did not think they had arrived at that stage yet. In the Punjab there was no officer who corresponded to the English inspector of nuisances: but he was training men to that end. Special plague officers were doing medico-surgical work, but they should be placed under the Sanitary Commissioner as their work came under the sanitation head. So far as administrative work was concerned the Sanitary Commissioner should be under the Inspector General of Civil Hospitals; but on technical matters connected with sanitation he objected to that and suggested that the Sanitary Commissioner should be independent. The awakening of public interest in sanitation was proceeding apace in India, and it had progressed so far as to justify a considerable increase in the staff.

Major J. C. Robertson, Sanitary Commissioner with the Government of India, advocated an all-India sanitary and bacteriological department. There was difficulty in attracting officers to the department, and at the present time there was an insufficiency of men available for the service. During the past year men outside the medical service had been recruited into the department, but it was too early yet to state any result of the experiment. It was essential that Indians should be recruited to the department, one of the objects in this being to arouse the interest of the people. At present he would, however, prefer European superior officers because of their wider knowledge. He would be disposed to give superior posts to the best of the Indians from the Indian medical colleges provided they went home for two or

three years and applied themselves to the study of sanitation, and thought there existed a good opening for the employment of women doctors. He laid stress on making the department more attractive.

Dr. A. Lankester, honorary secretary to the Medical Missionary Association of India, stated that he had 22 years' experience in medical work in this country and was of opinion that there should be a considerable increase in the staff of the medical service in India, and private agencies should be called in more and more to help the Government. He thought that the civil surgeons were overworked and that there was great scope for an increase in the *personnel* of the service. He thought there would be a great advantage in Government hospitals taking private practitioners as honorary surgeons. The initial benefit would be with the practitioner, but ultimately the gain would be a double one. He thought it most important that a Medical Act should be introduced into India. He advocated making the civil side of the Indian Medical Service the premier branch and recruiting from there into the military side. The normal condition was one of peace. To ease the present burden of our work he would place the non-medical charge of jails in the hands of non-medical officers. He advocated the abolition of private practice among civil surgeons, but would compensate them for their loss. He suggested that hospitals in districts should be placed under the charge of outside practitioners, and that in cities a certain number of beds should be placed under their charge.

THE HEALTH OF THE NAVY IN 1912.

THE statistical report on the health of the Navy for the year 1912 is the first to appear over the signature of Surgeon-General Arthur W. May, who became Director-General in the latter part of the present year. The returns continue to show an improvement for the Navy as a whole, which is extremely satisfactory. The total force for the year 1912 amounted to 119,540, of which number 92,120 were serving in the Home Fleet or on the home station, the remaining 27,420 being distributed among the seven fleets and squadrons serving abroad. For the Navy as a whole the number of cases of sickness has been 642 5 per 1000 of strength, compared with 666·6 for the preceding five years' average, 1907–1911; the daily sick have been 25 16, compared with 27·67; the deaths 3·30, compared with 3·24; and the final invalidings 16·92, compared with 16·44 per 1000. The last two items are very slightly in excess of the ratios for the year preceding, as well as of the quinquennial average. The highest admission ratio, 948 per 1000, occurred on the East Indies Station, but this was below the quinquennial average of 988, though considerably higher than the ratio for 1911—viz., 876. The deaths on this station (5·55 per 1000) were, on the other hand, very much below the average ratio of 9·43. The highest ratio of daily sick, 35·8, was met with, as usual, among the men on the Irregular List, including crews on passage to and from foreign stations, and those of the vessels on the west coast of America and on detached service. Next comes the Home Station, with an average of 33·75, and the East Indies Station with 33·51; while the healthiest command was that of the Home Fleet, with a daily sick ratio of 21·04 per 1000. The difference between the health of the Home Fleet and that of the Home Station was more marked than usual. The latter force consists of men at the depôts and on training ships, at the hospitals, and at the Royal Naval College at Greenwich.

The chief cause of admission to hospital was disease of the digestive system, with 111 admissions per 1000. Next after this came venereal disease, for which the ratio was 106 per 1000, a considerable improvement on the average for the preceding quinquennium, 1907–1911, which was 119·8; the average number daily sick, 6·14 per 1000, was also a reduction on the quinquennial ratio of 7·84. The other chief diseases of importance, such as pneumonia (3·74 admissions per 1000), malaria (2·55), and tuberculosis (2·32), were below the quinquennial averages; but for rheumatic fever there were 906 admissions, constituting a ratio of 7·57 per 1000, which is an increase on the preceding average of 6·95. The disease returned under this heading must, however, have been of a very mild type, as only one death occurred among the 906 cases. Mediterranean (formerly called Malta) fever has practically disappeared from the naval returns, there having been only four cases and no death. The most fatal disease was pneumonia, causing 36 deaths (0·30 per 1000); after which come enteric fever with 29 deaths (0·24) and tuberculosis with 22 deaths, and organic heart disease with the same number (0·18 per 1000). The chief causes of invaliding were heart disease (2·70), nervous diseases (2·45), and tuberculosis (1·83 per 1000); the last-named only is a reduction on the quinquennial average (2·06).

On comparing the figures for the different naval commands it is seen that the East Indies Station suffered most, having an admission ratio of 948 per 1000, with 45 invalidings and 5·55 deaths. Malaria caused 37·5 and pyrexia 12 admissions per 1000, the other chief causes of sickness being digestive and venereal diseases and affections of the skin and connective tissue. The healthiest commands were the Mediterranean with 503 and the Home Fleet with 556 admissions per 1000.

Prevalence of Chief Diseases.

The diseases of most frequent occurrence in the Navy may now be considered in regard to their prevalence and distribution. Before alluding to these it may be mentioned that only 3 cases of small-pox occurred throughout the whole force, 1 case from each of three ships on the China Station; one of these was fatal. In two instances the patients had to be retained on board ship for periods of six and seven days respectively. No extension of the disease occurred, in spite of the inevitable closeness of contact with the rest of the crew, a fact which speaks highly for the protection afforded by vaccination.

Influenza (1413 cases) caused less sickness than has been usual of late years; the admission ratio was 11·82, compared with 21·24 per 1000 for the preceding quinquennium. The disease itself was mostly of a mild type, and there were no deaths; it occurred in all the commands except the Cape, most of the cases being on the Home Station and in the Home Fleet. Scarlet fever prevailed in epidemic form on the Home Station, where there were 334 cases and 4 deaths; 199 cases were admitted from the boys' training ship *Impregnable*, the epidemic continuing throughout the year, but being of a mild type. Diphtheria was again, as in 1911, prevalent on the Home Station, 167 out of the total 194 cases being admitted from this command, and of these 107 occurred at the Shotley training establishment; none were of a severe character. Fleet-Surgeon R. H. Browne remarks that some of the carrier cases dealt with were extremely intractable to treatment, and an appreciable number developed diphtheria later. He did not find prophylactic inoculation to be "of any material value." Seven cases were returned by the *Donegal*, of the North American squadron, 6 being boys; these were attributed to infection from Shotley, carried in the clothing or bedding.

Enteric fever caused 140 admissions and 29 deaths. On the Home Station 18 cases occurred on board the *Vivid*, most of them probably contracted at Plymouth; in 4 instances, also in 5 cases on the *Impregnable*, the eating of shellfish was thought to be the cause. To a similar origin were attributed several cases in the Home Fleet. At Ascension Island 15 cases followed on the flooding of water catchment areas by heavy tropical rains, owing to which the drinking-water became polluted. On board the *Formidable*, of the Home Fleet, 10 cases occurred, without obvious connexion, but apparently originating within the ship. Fleet-Surgeon H. C. Arathoon made an exhaustive investigation, and inclined to the belief that the disease originated on board. No definite vehicle of infection could be discovered, but the yeast used in baking was found to contain bacilli of the coli group. It is probable that in many instances the temperature reached in the interior of a large loaf may not be high enough to destroy the bacilli. Of Mediterranean fever 4 cases only occurred throughout the whole Navy. One in the Home Fleet is stated to have been a sequela of an attack originally sustained in 1905; the other three were on the Mediterranean Station—one, a Maltese, who drank unboiled goats' milk at his own home; another, a sailor who developed the disease while in hospital in Malta suffering from pneumonia; for the third, who had not been ashore for more than a month, no explanation could be found. A greater number of deaths occurred from pneumonia than from any other disease—viz., 36, giving a ratio of 0·30 per 1000, slightly below the quinquennial average of 0·32. Of the 448 cases, 197 were

admitted on the Home Station (chiefly from the depôt and training ships) and 185 in the Home Fleet, but there was no epidemic prevalence. Malaria showed a decided reduction, compared with former years. There were only 306 cases in all, giving an admission ratio of 2·55 per 1000, little more than half that of the quinquennium (4·91); 81 cases were contracted at Bombay or in the Persian Gulf, but the ratio per 1000 (37·5) was much below that for the previous five years (132·45). Tuberculosis shows a slight improvement, the ratios for admission and death being 2·32 and 0·18 compared with 2·68 and 0·27 during the quinquennium; the sick berth staff, with 6·65, and the ships' stewards, with 4·66 admissions per 1000, suffered much more than the other ratings, for seamen the admissions being only 2·37; the least incidence was experienced by the ships' cooks (1·47). The East Indies Station, with an admission ratio of 5·09, suffered much more than any other. Venereal diseases, as already stated, have shown a substantial decrease, and do not now head the list with a larger number of admissions than any other disease. The improvement has been most noticeable in the admissions for primary and secondary syphilis. The total days' sickness from these two diseases has been less by 14,000 than in 1911, due to the use of salvarsan; the invaliding ratio for syphilis has also decreased from 0·89 to 0·69 per 1000. There were 107 cases of poisoning throughout the whole force; 42 of these were due to ptomaines, but no outbreak of any importance is recorded; 22 were due to carbon monoxide, mostly owing to working in coal bunkers. Death from drowning occurred in 79 instances, of which 29 were due to the loss of submarines A 3 and B 2.

The appendix contains an account of some interesting cases of Gunshot Injury in China, by Surgeon D. H C. Given; Some Observations on X Rays in the Diagnosis of Tubercle of the Lung, by Surgeon R. Connell; Statistical Results of the Use of Salvarsan, by Fleet-Surgeon L. Kilroy; and an account of the Seven-day Fever of Indian Ports, by Surgeon D. A. Mitchell.

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enteric Fever in the Borough of Colne (Lancashire), by Dr. J. R. HUTCHINSON.[1]—This report relates to an outbreak of enteric fever due to milk infection which occurred in Colne, a Lancashire town with a population of 26,000, between Dec. 21st, 1912, and Feb. 1st, 1913. Altogether 74 cases were notified, and 54 houses were affected. Deducting the first case of all and three secondary cases—i.e., those occurring in invaded houses in which illness did not begin for more than a fortnight after the first case, there remained 70 cases which had the implicated milk-supply in common. The age distribution of these cases was as follows:—

1 to 10 years	20	31—40 years	4
11 „ 20 „	16	Over 40 „	8
21 „ 30 „	22		70

Thirty-four were males and 36 females. The daily rounds of the milk dealer in question and the sources from which his milk was obtained were investigated in detail by Dr. Hutchinson and by Dr. W. Doyle, the medical officer of health of Colne, and the source of infection was traced to a particular dairy farm at which a schoolgirl in the farmer's household had been nursed at home on account of illness the true nature of which was not recognised from Dec. 5th, when she first sickened, until the end of the month, when she was regarded as more or less convalescent. She was, however, found still to be ill on Jan. 14th, when she was removed to hospital. Dr. Hutchinson notes as to the opportunities of infection of the milk during this period, that the milk used by the farmer's family was extracted by a jug from the large "kit" in which milk was sent away to the town, and that the same dish-cloth was used for this jug, for other domestic crockery, and for the milking cans. The girl's mother, who conducted these cleansing operations, slept with her sick daughter and attended to all her wants during illness. The report has a useful diagram of cases and a map showing in a striking manner the way in which the invaded houses followed the line of the particular milk distribution. The text of the report forms an interesting narrative, setting out the facts and conclusions in logical order, and leaving no doubt of the thoroughness with which the investigations were conducted at every stage. Dr. Doyle's prompt action in stopping the milk-supply as soon as suspicion was directed to the farm concerned should receive grateful recognition from the inhabitants of the district.

On Conditions of Housing and other Sanitary Circumstances in St. Dogmell's Rural District, by Dr. MORGAN J. REES.[2]—The problem of the derelict country district is just now very prominently before the public in connexion with a host of remedies and panaceas, in nearly all of which the provision of better cottages for the agricultural labourer is aimed at. The social, economical, and industrial features of this question are admittedly complex, and their right solution must depend upon the proper appreciation of the facts as they now are in representative districts. From this point of view Dr. Rees's report on the part of Pembrokeshire contained in the rural district of St. Dogmells is distinctly valuable. It is a large district 15½ miles by 10½, badly served by railways, with a total population in 1911 of 7888—a decrease of 364 on the previous Census. Most of the people live in scattered villages and hamlets, the country has been turned down to grazing for cattle and sheep, and the farm labourer gets low wages, 7*s.* 6*d.* to 12*s.* 6*d.* a week, plus his own food at the farm and a furrow of potatoes. Usually he has to pay his own house rent; as many as 1475 out of the 2297 occupied houses in the district are rented at under £5 per annum. The ordinary cottage is built of flat slaty stone on the bare earth, without foundations or damp-proof courses, the stones of the thick walls being bound together by friable material and showing holes and crevices. They are roofed with similar stone, sometimes without guttering or eaves spouting; the yards about them are usually unpaved, and it is common for them to be built back-to-earth against the hillside. Some contain a single large room only; others contain lofts, used as sleeping-rooms, which are very low and lighted and ventilated (if such terms can be used) only by a small skylight. Dr. Rees gives a detailed description of 12 cottages as typical of a large number, with particulars of the number of occupants, wages, house-room, and cubic space. The description is certainly forbidding, and little exercise of imagination is necessary to realise the unwholesome nature of the accommodation available. In addition, it appears that many of the duties of an active sanitary authority, such as looking after the purity of the water-supplies or the scavenging of the villages, are neglected. The occasion of the inspection is noteworthy; it resulted from the district council inviting the central authorities to take a wide view of the position and ameliorate housing conditions from Imperial funds. Till such aid was given the council practically declined to put in force the provisions of the Housing and Town Planning Act of 1909, either in respect of the systematic inspection of houses required by the regulations made by the Local Government Board under that Act, or in regard to the provision of new dwellings. As might be expected, the Local Government Board was unable to accept the plea, and certainly Dr. Rees's report demonstrates that there is urgent necessity for systematic inspection of houses and the application of the Housing Acts. The district council would command greater sympathy and have better ground for their claims to assistance from the taxpayer if they were to make a serious attempt, however limited, to carry out their statutory duties in sanitary matters. The publication of this report may, and we hope will, enable the local authorities to make a new start on better lines.

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 11·0 per 1000 of the population, estimated at 4,518,191 persons in the middle of the year; in the three preceding months the rates were 5·4, 7·7, and 10·4 per 1000 respectively. The lowest rates last month were recorded in Hampstead, St. Pancras, the City of London, Stepney, and Wandsworth; and the highest rates in Fulham, Southwark, Bermondsey, Lambeth, Camberwell, Deptford, and Woolwich. The prevalence of scarlet fever again showed an increase over the high numbers recorded in other recent months, and was greater than in any preceding month of the year; this disease was proportionally most prevalent in Hammersmith, Fulham, Islington, Southwark, Bermondsey, Lambeth, Battersea, Camberwell, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 1033, 1610, and 2562 at the end of the three preceding months, had declined to 2323 at the end of last month; the weekly admissions averaged 581, against 258, 402, and 512 in the three preceding months. Diphtheria was slightly less prevalent than in the previous month; the greatest proportional prevalence of this disease last month occurred in Paddington, Fulham, Holborn, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 1188 diphtheria patients at the end of last month, against 909 and 1190 at the end of the two preceding months; the weekly admissions averaged 158, against 147 and 184 in the two preceding months. The prevalence of enteric fever showed a slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in St. Marylebone, Hackney, Finsbury, Stepney, Poplar, Southwark, Bermondsey, and Lewisham. There were 72 enteric fever patients under treatment in the Metropolitan Asylums Hopitals at the end of last month, against 37, 56, and 77 at the end of the three preceding months; the weekly admissions averaged 11, against 6, 11, and 12 in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Deptford. The 29 cases of puerperal fever notified during the month included 6 in Wandsworth, 3 in Fulham, 3 in Islington, 3 in Poplar, 3 in Lambeth, 2 in Hackney, and 2 in Stepney. Of the 3 cases of cerebro-spinal meningitis, 2 belonged to St. Marylebone and 1 to Fulham; and of the 15 cases of poliomyelitis 4 belonged to Wandsworth and 2 to St. Pancras.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the several boroughs. During the four weeks ending Nov. 29th the deaths of 4678 London residents were registered, equal to an annual rate of 13·5 per 1000; in the three preceding months the rates had been 11·8, 13·3, and 13·7 per 1000 respectively. The death-rates last month ranged from 9·1 in Lewisham, 9·7 in Wandsworth, 11·1 in Holborn, 11·6 in Hammersmith and in Hampstead, and 12·0 in Kensington, to 15·1 in Poplar, 15·2 in the City of London, 15·6 in Bethnal Green, 16·2 in Stepney, 16·3 in Southwark, 17·6 in Shoreditch, and 19·5 in Finsbury. The 4678 deaths from all causes included 320 which were referred to the principal infectious diseases; of these, 13 resulted from measles, 13 from scarlet fever, 40 from diphtheria, 30 from whooping-cough, 7 from enteric fever, and 247 from diarrhœa and enteritis among children under two years of age. The lowest death-rates from these diseases were recorded in Kensington, Hammersmith, Hampstead, Wandsworth, and Woolwich; and the highest rates in Paddington, Holborn, Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Bermondsey. Only 13 fatal cases of measles were recorded last month, the corrected average number for the corresponding period of the five preceding years being 168; these 13 cases included 2 in Shoreditch, 2 in Bethnal Green, 2 in Southwark, 2 in Bermondsey, and 2 in Camberwell. The 13 deaths from scarlet fever were 11 below the corrected average number, and included 2 in Southwark and 2 in Camberwell. The 40 fatal cases of diphtheria were 14 fewer than the corrected average number, and included 4 in Poplar, and 3 each in Paddington, Islington, Lambeth, and Camberwell. The 30 deaths from whooping-cough showed a decline of 15 from the corrected average number, and included 5 in Bethnal Green and 3 in Paddington. The 7 fatal cases of enteric fever showed a decline of 11 from the corrected average number, and belonged respectively to Hackney, Stepney, Poplar, Bermondsey, Lambeth, Greenwich, and Lewisham. The mortality from diarrhœa and enteritis among children under two years of age was proportionally greatest in Finsbury, Shoreditch, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was equal to only one-third of the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Hugh Winkworth Macnamara has been placed on the Retired List at his own request.

The following appointments have been notified:—Staff-Surgeons: E. M. W. Hearn to the *Pembroke*, additional, for Chatham Hospital, and as Anæsthetist and Radiographer. J. McCutcheon to the *Hazard*; B. Pick to the *Ganges*, additional, for Shotley Sick Quarters; and A. La T. Darley to the *St. George*. Surgeon: C. R. M. Baker to the *Cornwall*.

ROYAL ARMY MEDICAL CORPS.

Surgeon-General W. Babtie, V.C., C.B., C.M.G., Deputy Director-General Army Medical Service at the War Office, has been selected for appointment as Director of Medical Services to His Majesty's Forces in India, in succession to Surgeon-General A. T. Sloggett, C.M.G., honorary surgeon to His Majesty the King.

Colonel W. G. Macpherson, C.M.G., Assistant Director of Medical Services to the Fourth (Quetta) Division of the Southern Army in India, has been selected for appointment as Deputy Director-General Army Medical Service at the War Office. Colonel W. G. Bedford has been selected for appointment as Deputy Director of Medical Services in South Africa, in succession to Surgeon-General O. E. P. Lloyd, V.C., C.B., retiring under the age limit.

Lieutenant-Colonel M. W. Russell, Deputy Assistant Director of Medical Services to the Eastern Command, has been granted leave of absence for one month prior to embarking for Malta for a tour of service. Lieutenant-Colonel G. A. T. Bray, recruiting medical officer at Canterbury, has been selected for appointment as Deputy Surgeon to the Royal Hospital at Chelsea. Lieutenant-Colonel M. P. C. Holt, D.S.O., honorary surgeon to the Viceroy and Governor-General of the East Indies, has been appointed Senior Medical Officer on board the transport ss. *Plassy*, leaving Bombay for Southampton on Jan. 9th, with invalids and time-expired troops.

Major S. A. Archer has been placed under orders to join the Irish Command on Dec. 28th, and on arrival will be appointed to the Belfast District for duty. Major J. E. Hodgson has been transferred from the London District to the Northern Command and appointed Specialist Sanitary Officer at Headquarters, York. Major H. W. H. O'Reilly has been placed under orders for a tour of duty with the Ninth (Secunderabad) Division in India. Major G. St. C. Thom has been selected for appointment as Deputy Assistant Director of Medical Services to the Lowland Division vice Major W. D. Erskine. Major B. F. Wingate has joined the London District. Major M. Swabey and Major H. K. Palmer have been detailed for duty on board the transport s.s. *Rewa*, which left Aden on Dec. 15th. Major E. W. Slayter has been directed to join the Irish Command on Jan. 12th for duty in the Cork District. Major A. W. N. Bowen has been appointed to the Belfast District. Major W. M. Power has been selected to hold charge of the Military Families Hospital at Chatham. Major J. F. M. Kelly has been granted six months' leave of absence from Colchester on medical certificate. Major G. A. Moore has been selected for appointment as Specialist in Otology and Laryngology to the Aldershot Command. Major J. H. Campbell, D.S.O., has been selected for appointment as Medical Inspector of Recruits to the Eastern Command. Major P. S. O'Reilly has been appointed to the Royal Arsenal at Woolwich.

Captain H. B. Connell has been appointed to Shrewsbury. Captain A. S. Arthur has been transferred from Liverpool to Wrexham. Captain A. W. Howlett has been appointed to the Military Hospital at Bareilly Cantonment. Captain G. F. Rudkin has joined at Dublin. Captain W. E. C. Lunn has been detailed for duty on board the transport s.s. *Dongola* to leave Karachi for Southampton on Dec. 19th. Captain H. J. Crossley has embarked for a tour of service in India. Captain N. E. J. Harding has joined the London District for duty. Captain R. C. Fellowes has been transferred from Omagh to the Military Hospital at Holywood and appointed to hold medical charge of the 1st Norfolk Regiment. Captain J. A. W. Webster has been placed under orders for a tour of service with the Fifth (Mhow) Division of the Southern Army in India. Captain A. E. S. Irvine has joined the Royal Army Medical College on transfer from the Belfast District. Captain F. L. Bradish on return home from Jullundur Cantonment, tour expired, has been appointed to the Military Hospital at the Curragh. Captain T. W. Browne has taken up duty in the Cork District. Captain R. H. MacNicol has been placed under orders to embark for service in Malta. Captain J. L. Wood has joined the Northern Command. Captain M. Keane has been placed under orders to proceed to India for a tour of service. Captain G. S. Wallace has been appointed to the Military

Hospital at Bellary Cantonment, Madras. Captain A. M. Rose has been transferred from the Military Hospital at Bordon to Longmoor. Captain G. H. Rees has taken up duty at Londonderry on transfer from Ballykinler. Captain G. P. A. Bracken has been appointed to the Northern Command on return home from Malappuram Cantonment. Captain F. C. Lambert has been placed under orders for a tour of duty with the Sixth (Poona) Division of the Southern Army in India. Captain A. L. Otway has been appointed Specialist Sanitary Officer to the Southern Command. Captain J. du P. Langrishe has been appointed for duty at Spike Island, Queenstown, on arrival home from Kirkee Cantonment. Captain L. A. A. Andrews has been transferred from the Military Hospital at Cork to the Northern Command for duty at York. Captain C. W. Holden has been appointed for duty to Queen Alexandra Military Hospital at Grosvenor-road, S.W. The following Captains have joined the Royal Army Medical College for the courses of instruction for promotion to the rank of Major: G. B. F. Churchill (Bulford), H. E. Priestley (Tidworth), H. Stewart (Halifax), J. S. Dunne (Woolwich), A. S. Littlejohns (Dublin), W. Egan (Curragh), and A. S. Williams (Kilbride).

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel S. E. Prall, health officer to the Port of Aden, has been granted leave of absence home. Lieutenant-Colonel R. Bird, M.V.O., C.I.E., has returned to India from leave of absence home. The services of Lieutenant-Colonel T. E. Dyson have been placed at the disposal of H.E. the Commander-in-Chief in India. Lieutenant-Colonel P. B. Haig has been granted two years' furlough and combined leave of absence home from India. Lieutenant-Colonel R. G. Turner has been transferred from Naini Tal to Moradabad and appointed Civil Surgeon. Lieutenant-Colonel J. Penny has been granted four months' extension of leave of absence home from India on medical certificate.

Major W. G. Richards has joined at Salem. Major A. F. W. King has been appointed by H.E. the Governor of Bombay to officiate as Civil Administrative Officer at Aden. Major E. C. Macleod has been selected for advancement to the rank of Lieutenant-Colonel. Major W. E. McKechnie, civil surgeon at Etawah, has been granted two years' furlough combined with general leave of absence home from India. H.E. the Governor of Bombay has selected Major F. H. G. Hutchinson on return from leave of absence for appointment as Sanitary Commissioner to the Bombay Presidency, in succession to Lieutenant-Colonel T. E. Dyson. Major W. G. Hamilton has been appointed Superintendent at the Alipore Central Jail during the absence on leave of Major F. S. C. Thompson. Major R. P. Wilson has been transferred to Calcutta and appointed Superintendent at the Campbell Medical College, Calcutta. Major T. McGilchrist has been appointed to officiate as Civil Surgeon at Rampore Boalia.

Captain H. M. H. Melhuish has arrived home on leave of absence from India. Captain N. M. Wilson has taken up duty at Dera Ghazi Khan. Captain G. L. C. Little has been granted four months' extension of leave of absence home from India on medical certificate. Captain M. D. A. Kureishi has been appointed to officiate as Civil Surgeon at Aden in succession to Major A. F. W. King. Captain W. S. Nealor has been placed on special deputation to the X ray Institute at Dehra Dun for a course of instruction. Captain M. White has been appointed to hold collateral charge of the Civil Surgeoncy in the Shwebo District during the absence of Captain W. S. Nealor. The services of Captain O. A. R. Berkeley Hill, officiating superintendent of the Punjab Lunatic Asylum, have been replaced at the disposal of the Government of India in the Home Department on relief by Lieutenant-Colonel J. Ewens on return to duty from leave of absence. Captain E. P. Wernicke, on special duty at Pachmarhi, has been posted to the Seoni District as Civil Surgeon and appointed to the executive and medical charge of the Seoni Jail. Captain R. F. Hebbert has been granted two months' extension of leave of absence home from India. Captain R. E. Flowerdrew has been appointed to officiate in the Jail Department in Madras.

Lieutenant C. M. Plumptre has been appointed to officiate as Agency Surgeon in Bhopal State.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Cadet-Corporal Samuel Griffin, from the Royal College of Surgeons in Ireland Contingent, Officers' Training Corps, to be Lieutenant (on probation) (dated Nov. 21st, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

Major Thomas C. MacKenzie, D.S.O., Royal Army Medical Corps, is appointed a Deputy Assistant Director of Medical Services of a Territorial Division (dated Nov. 5th, 1913).

Captain William George Maydon, Royal Army Medical Corps, to be an Adjutant of a School of Instruction, vice Major William M. H. Spiller, who vacates that appointment (dated Nov. 12th, 1913).

1st East Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant Albert Ramsbottom to be Captain (dated Nov. 14th, 1913).

3rd East Lancashire Field Ambulance, Royal Army Medical Corps: Lieutenant Edward H. Cox to be Captain (dated Nov. 14th, 1913).

1st Northumbrian Field Ambulance, Royal Army Medical Corps: Captain Frank Hawthorn to be Major (dated Dec. 13th, 1913).

2nd West Riding Field Ambulance, Royal Army Medical Corps: Robert Garside Dixon to be Lieutenant (dated Nov. 1st, 1913).

3rd Welsh Field Ambulance, Royal Army Medical Corps: Lieutenant William A. T. Lloyd resigns his commission (dated Dec. 13th, 1913).

Attached to Units other than Medical Units.—Captain John G. Martin to be Major (dated Oct. 26th, 1913). Lieutenant Noel W. Kidston to be Captain (dated Nov. 1st, 1913). Lieutenant James W. McIntosh resigns his commission (dated Dec. 13th, 1913).

For Attachment to Units other than Medical Units.—William George to be Lieutenant (dated Dec. 13th, 1913). Captain Lionel H. Moiser resigns his commission (dated Dec. 10th, 1913).

TERRITORIAL FORCE ASSOCIATION OF THE COUNTY OF LONDON.

According to the annual report of Colonel Valentine Matthews, the County Director of the London Voluntary Aid Detachments, 79 detachments, with a *personnel* of 2230, were registered on Sept. 30th. This shows a slight increase for the year, although four detachments have been disbanded. The work done seems to have been distinctly progressive and encouraging. With regard to a recent War Office regulation to the effect that a medical officer and a pharmacist may be included in the establishment of a Women's Voluntary Aid Detachment, provided only women holding those qualifications are enrolled, this will, in the opinion of Colonel Matthews, impede rather than assist the development of the scheme of voluntary aid. He hopes that the restriction as to sex will be rescinded. He also expresses the opinion that the county director and commandants of detachments should be brought into closer unofficial relation.

STAFF TOUR FOR MEDICAL SERVICES.

Arrangements have been made by the Commander-in-Chief in Ireland to hold a Medical Staff tour under the direction of Surgeon-General L. E. Anderson, C.B., Deputy Director of Medical Services, Irish Command. The following officers have been selected for appointment on the directing staff:—Colonel R. H. S. Sawyer, Assistant Director of Medical Services to the Dublin District; Lieutenant-Colonel H. B. Williams, D.S.O., General Staff; Lieutenant-Colonel C. Dalton, Deputy Assistant-Director of Medical Services, Irish Command; Major J. H. Brunskill, specialist sanitary officer, Dublin District. Attached: Lieutenant-Colonel E. F. Taylor, Army Service Corps; Major W. Trail, Royal Engineers; and Captain G. Harding, Army Service Corps. Royal Army Medical Corps officers taking part in the tour are: Colonel H. M. Sloggett, Lieutenant-Colonel H. D. Rowan, Majors H. S. Thurston, S. G. Butler, N. J. C. Rutherford, A. W. A. Irwin, and F. P. Lauder, and Captains H. B. Kelly and T. H. Gibbon.

Colonel J. J. Pratt, I.M.S., has been appointed surgeon to the Seamen's Hospital Society (Dreadnought) with duties at the Albert Dock Hospital, to which is attached the London School of Tropical Medicine.

LITERARY INTELLIGENCE.—In a few days' time Messrs. J. and A. Churchill will publish the Medical Directory for 1914. In the year 1844 Mr. John Churchill, the grandfather of the present partners of the firm, issued the first of the series of volumes destined to occupy a permanent place on the shelves of so many practitioners. To celebrate its seventieth birthday the publishers have printed all names and addresses in black type. It is believed that this will arrest the eye and facilitate the work of ready reference.—Messrs. George Routledge and Sons announce the forthcoming publication in January, 1914, of a "Handbook of Photomicrography," by H. Lloyd Hind, B Sc., F.I.C., and W. Brough Randles, B.Sc., lecturer in biology, Derby Technical College, containing an account of the modern methods employed in photomicrography, with a description of the apparatus and processes used in the photography of small objects, from natural size up to the highest magnifications, stereoscopic photomicrography, cinematomicrography, and colour photomicrography.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1721.*)

XXXI.—THE STRUGGLE IN WALES BETWEEN THE PANEL AND THE INSTITUTIONS.

THE possibility of withholding from panel service has hardly been entertained in the South Wales and Monmouthshire industrial and mining districts. In the mining villages private practice is regarded as possibly bringing in from £10 or £15 a year, and its chances are almost disregarded. The practitioner lives by contract work, and what little private practice there used to be is rapidly disappearing. In this respect a very important economic revolution is taking place which may alter the commercial conditions seriously. The individual or private tradesman is disappearing. The substantial grocer who could afford to pay fees to his medical attendant is everywhere being replaced by the salaried manager of some coöperative store or the representative of a big firm or company that has branch shops all over the district. Instead of dealing with independent tradesmen the medical practitioner has to deal with the employees of these great trading concerns, whose salaries do not reach the income-tax limit. These poorly paid shopmen cannot consult independent practitioners; they are themselves insured. This means a change in the money distribution of the country, converting the independent inhabitants of whole districts into persons employed for wages. In itself this is a very serious social and economic revolution, and its effect on independent medical practice has been disastrous. Some 20 years ago these "multiple shops," as they are called, were unknown in, for instance, the Rhondda. Now they abound on all sides, so that the private tradesman is a distinctly rare character. Already private practice is so scarce that many medical men have lost the habit of keeping accounts; some of them might get more from the private practice which they actually do if they remembered more accurately all visits for which they ought to send in bills. In such circumstances it was useless to expect the South Wales colliery doctors to go on strike against the Insurance Act. They disliked certain of the proposals of the measure, and many thought it would be found in practice that the old poundage system paid better than the new scheme; but the representatives from South Wales always warned the British Medical Association that whatever resolutions were passed a large number of practitioners would nevertheless be obliged to go on the panel. It was only at Cardiff, where there is some private practice, that a difficulty arose in forming the panel.

But with the purely rural practitioners of South Wales and Monmouthshire, as distinct from the colliery surgeons, the conditions are different, and there is not the same necessity to join the panel. Therefore, preparations were made to send down two medical men for whole-time service in Monmouthshire, but the practitioners of the industrial districts undertook to help the rural practitioners in the question of mileage or the difficulty of calls to long distances, and both parties ultimately agreed to follow the same policy—to go on the panel and there support each other.

Negotiations for the Dependents.

In the Eastern Valley, Monmouthshire, representatives of the workmen asked the local practitioners to state their terms for the dependents. The latter replied that there should be a poundage of 2½*d.* instead of 3*d.* as formerly. For reasons already explained 2*d.* may be thought enough; but the argument was brought forward that the 7*s.* from insured persons did not cover the 10*s.* 6*d.* for confinements and abortions, major surgery, &c. The medical men further asked that the question of numerous certificates should be considered. Formerly the men belonged to one club and only needed one certificate. Now they had two or three clubs, and there were the certificates for compensation and accidents, and these had to be renewed every week the patient was invalided. Also a patient must take a note to his works when he returns to show that he was legitimately entitled to be absent; thus five or six certificates are sometimes needed, while under the system prevailing before the Act only one certificate was necessary. All this takes up much time. Then the wife will come round for a certificate so as to keep her child from school. A practitioner has thus urgent need to employ a clerk. The doctors further submitted the question of strikes, during which period they had to do all their work gratuitously. During the last great strike some of the colliery doctors in the North of England were paid, but in Monmouthshire and South Wales not a penny was received.

When these points were submitted the men would not agree to any of them. The doctors thereupon withdrew the question of certificates and of strikes, and the men's representatives then replied that if the doctors would be content with a poundage of 2*d.* they would strongly advise the acceptance of the terms. The doctors surrendered the halfpenny, and their patients were warm in their thanks at first for the concession. But later they thought of another and a new point which they wanted the doctors to concede. It was that the money, collected according to the poundage system by the clerk or wage payer at the works, should be sent, not to the doctors to whom it was due, but to the workmen's committee. The men offered to hand over the cheque in full to the doctors, but if they were not going to take any of the money why should they have the cheque? This seemed to be an intention to acquire a hold over the doctors of an illegitimate and dangerous kind, and the medical profession absolutely refused to allow it. For the sake of harmony they had proved their readiness to make a considerable financial concession, and had in other ways shown a wish to be friendly, but the members of a highly trained profession could not place themselves at the beck and call of a workmen's committee to the extent that such a power over the purse as was desired would give.

Refusal to Serve Workmen's Committees.

Very similar negotiations took place in South Wales. At Briton Ferry and Neath representatives of the medical profession and of the workmen met to arrange terms for attendance on the uninsured, as, according to the policy of the British Medical Association, notice had been given to terminate all contracts by Jan. 15th, 1913. Here the men had substituted a flat rate of 3*d.* a week for all workers, married and unmarried, and their dependents. After the Act the doctors asked for 10*d.* for four

weeks instead of the shilling paid formerly. This was met by saying that the single men, being now insured, refused to make any other payment, and the men wanted to fix a price for the families only. The doctors then asked the lowest figure approved in one of the public medical service propositions formulated by the British Medical Association—namely, 1*s.* 4*d.* per month per family. These terms might have been accepted, but the men insisted that the doctors should work under the control of a committee elected by the working men, and all the money was to go through the hands of this working man's committee. A deadlock ensued. The doctors did not consider that such a committee possessed the right or the capacity to secure such control.

A certain number of influential working-class men and leaders thereupon set to work to form schemes; and, unfortunately for them and all concerned, were encouraged in their course by the Welsh Commissioners. Thus at Briton Ferry, as early as March this year, the local trades and industries formed a committee. After holding several meetings at different works and electing representatives this committee called itself the Briton Ferry Workmen's and General Institution for Medical and Surgical Treatment. They were recognised by the Insurance Committee as a system under Section 15, Clause 3. They began to provide medical aid on April 15th—that is, three months after the Act had come into force—though Clause 4 of the same section of the law only recognises systems that were in existence before the adoption of the Act. To the lay mind this all seems highly irregular, but I do not attempt to decide upon what the legal discretions of an extraordinarily powerful public department may be.

Disastrous Effect of Schemes under Clause 3.

The managers of the Briton Ferry scheme advertised for doctors and appointed two whole-time men, one at £350 and the other at £250 a year. They claim to have about 2000 insured persons as members, and at 9*s.* this represents £900, a part of which sum comes from the British taxpayer—i.e., from the entire community, yet it is allowed to go into the coffers of a private and uncontrolled association or enterprise. The medical men must also attend on the dependents of the insured. The association tries to get 1*s.* per month for every family, but whether it succeeds or not the medical staff get no extra pay for attending on the families. It provides the surgery and the drugs, but does not house the medical officers. The scheme receives under the Act £900 a year for 2000 insured persons, and pays £600 a year to the medical men for attending to a population that includes the dependents on the insured. The total population of Briton Ferry now amounts to close upon 9000 persons, and of these 3000 are insured. As the scheme takes over 2000 of the insured with their dependents, it provides medical aid to two-thirds of the entire population. There is therefore only one-third of the population remaining for the panel doctors. Formerly there were two panel doctors who each employed an assistant. These two local practitioners with their assistants attended to the entire population of 9000. Now that the scheme has taken away from them two-thirds of their panel practice, they have lost much of their income, and have been compelled to dispense with the services of their assistants.

This is a good illustration of the devastation these institutions may bring about, and there are seven such schemes in Glamorganshire, though fortunately they are not proportionately as mischievous. Nowhere has the individual practitioner and panel doctor been hit so hard as at Briton Ferry, and I am extremely glad to have been able to investigate the situation on the spot. Close to, at Neath, a similar system was started, but though they have to deal with a larger population they only employ one medical officer and have not secured more than 1000 insured persons as members. At Port Talbot, likewise close at hand, a system was attempted, but notices were issued to the medical profession with the result that no one applied for the post of medical officer. It is indeed surprising that these schemes are able to recruit any sort of medical staffs. Larger incomes than any salaries which such organisations will ever offer can now be easily obtained in highly reputable positions, and the contracting-out institutions will have only themselves to thank if they find that they secure inferior service. Good service can command better pay. I cannot attempt to explain why medical men with good reputations should accept a salary of £250 a year from an institution when, if they went on the panel in a populous district of an industrial centre where the panel is not overstocked, they would soon make much more, while preserving their professional position and independence. Nor is it easy to understand why workmen and their families join such schemes and run the risks attached to them. As a matter of fact, many workmen have found out their mistake and are very anxious to leave the schemes to which they belong and return to their old works doctors who are now the panel doctors. Many medical practitioners have expressed the opinion that by the mere force of superior merit the panel doctors could beat the institutions out of the field if there was fair play and if no underhand pressure was brought to bear on the public. The view has certainly a substantial foundation. In the Eastern Valley, for instance, I found that one single practitioner had a hundred transfers from members of the local scheme; but no one knows how many transfers there may be from panel doctors to this and other schemes. Many practitioners protested to me that these schemes would not be successful but for the unfair pressure exercised on ignorant or indolent people, and which has become possible because of the attitude of the Welsh Commissioners.

The Resistance against the Institutions.

In the Eastern Valley a scheme has been working since May, and its promoters are lucky in having, as yet, no scandalous breakdown to explain. The absence of epidemics has been fortunate for them, but even in quiet times some startling complaints have been made. At Blaenavon there is a scheme that absorbs three-quarters of the entire population, so the panel doctors and chemists are hit very hard. This scheme has imported six medical men, and, one having left, is now employing at fixed salaries five doctors to do the work which has been taken away from the 11 old-established local practitioners. In urgent or serious cases some of the insured members of this scheme have returned to their old doctors and paid full fees. When asked why they had joined the scheme they replied they had been compelled. They feared they might be persecuted if they refused. Now this sort of thing is entirely contrary to the spirit of the Act, and defeats every clause, section, and regulation devised to secure the best medical

attention by the best available man for the insured public. A notice should be put up in all the collieries and works to the effect that the employed are free to select their medical adviser and that they run no risk of losing their employment if they exercise this freedom. The local practitioners are demanding fair play, and even under the present conditions of pressure the workmen are leaving the institutions and the imported medical officers to return to their old doctors, with whom they have had life-long friendly relations and whom they have learnt to trust. The majority of the working men never wished for any change, and many, though belonging to these working men's organisations, consult their old doctors and pay them full fees.

The rise of these institutions has been very simple. Their secretaries get a wholesale supply of transfer forms and fill in the names. Protests have been made that this is occasionally done without the consent of the persons concerned. Letters to this effect were sent to the Insurance Committee of Glamorganshire and to the Welsh Insurance Commissioners. The former body replied that there was not much in the complaint, and were then told there were several witnesses ready to testify. To this an answer was given that an investigation would be made; but though this was said last July, nothing has been done. It is maintained that several persons have been transferred to schemes without their knowledge. The authorities seem to help insured persons to join the institutions, but make it difficult for them to return to the panel doctors; thus they appear to use their influence against the interests of the Act and of the general public. If an insured person desires to leave an institution he must draw up and send a written notice according to the rules of the institution in question, but if he wishes to transfer from his panel doctor to an institution he is not obliged to write out some special notification.

Fortunately, there is an easy means of putting an end to all these grievances. As indicated in my previous article, the example given by the staff of the Swansea General Hospital must be followed throughout the country. When members of these institutions or schemes find that they will be refused advice or admission at the hospitals there will be a general stampede of membership. The conspiracy to defeat the Act by allowing collectivities to contract out of the Act will fall to pieces, and the patients will be restored to the panel doctors.

(To be continued.)

UNIVERSITY OF BRISTOL: LONG FOX LECTURE.—The eighth of this series of annual lectures was delivered recently in the Physiological Theatre by Dr. F. H. Edgeworth, who chose as his subject the Motor Nuclei and Muscle-sensory Fibres of the Cranial Nerves. He described various ingenious experimental and other investigations by which he had been enabled to prove the presence of this type of fibre in the facial and other cranial nerves; researches which, with those of other workers, had proved or shown probable the existence of such fibres in all the cranial nerve-supplying muscles. The second part of his lecture dealt with the classification of the motor centres in the pons and medulla, showing that the usual division into a central somatic and a lateral splanchnic group is not strictly justified, since the lateral group contains somatic as well as splanchnic nuclei. Considering the abstruseness of the subject, the lecture was remarkably lucid, a result to which some excellent diagrams contributed largely. Sir Felix Semon, who was among the audience, congratulated the lecturer, adding some comments as to the innervation of the laryngeal muscles.

Home and Foreign Notes.

LIVERPOOL.

Tuberculosis Scheme.

LIVERPOOL, I believe, has the honour of being the first city to formulate a complete scheme for the prevention and treatment of tuberculosis. The scheme has been approved by the Local Government Board and the Insurance Commissioners. The objects of the scheme have been tabulated as follows:—

1. That it should be available for the whole community.
2. That those means which experience has proved to be most effective should be adopted for the prevention of the disease.
3. That a definite organisation should exist for the detection of the disease at the earliest possible moment.
4. That within practical limits the best methods of treatment should be available for all those suffering from the disease.
5. That concurrently with the measures for prevention, detection, and treatment, provision should be made for increasing the existing knowledge of the disease and of the methods for its prevention, detection, and cure by way of research.

There will be a temporary central dispensary at the Consumptive Hospital, Mount Pleasant; a south dispensary at 4, Dingle Hill; and a north dispensary at 330, Netherfield-road North. Nursing of insured persons and their dependents receiving domiciliary treatment has been undertaken by the Queen Victoria Nursing Association. The Jewish board of guardians have agreed to provide institutional treatment for members of their community at the Daneswood Sanatorium, Woburn Sands, Bedfordshire. The hospital beds that are available or that are contemplated are at the corporation sanatoriums, Parkhall, 200; Fazakerley, at present 80, to be ready soon 350. At voluntary institutions: Kingswood Sanatorium, Delamere, 40; the Chest Hospital, Mount Pleasant, 30; Royal Southern Hospital, 26; Northern Hospital, 28; the Royal Infirmary, 20; the Stanley Hospital, 10; the Infirmary for Children, 12; the Children's Convalescent Home, West Kirby, 50; the Country Hospital for Children, Heswall, 53; Sanatorium for Children, Leasowe (building), 100, increasing to 200; the Children's Rest (not stated). The Local Government Board are prepared to make grants to the council in accordance with the recommendation of the Departmental Committee: for dispensaries four-fifths of the amount required for the provision and equipment, provided that this sum does not exceed £1 per 750 population, or an average of £240 per dispensary; for additional sanatorium beds for adults three-fifths of cost per bed, provided the total sum contributed out of Government does not exceed an average of £90 per bed; the grants for other beds have not yet been fixed. The approximate annual cost of the scheme is close on £40,000 per annum, the largest part (£25,000) being for 350 beds for pulmonary consumptives, £6500 for 200 beds for tuberculous children, 40 beds for tuberculous adults at voluntary hospitals £2860, and the three dispensaries £2550. This expense will be defrayed by a grant from the Insurance Committee £8250, from the Treasury £15,580, and from the rates £15,580, so that the rates will be increased by about £7580, as £8000 is already being expended. The increase is equivalent

to ½d. on the rates. In connexion with this scheme it is proposed to make alterations at the Fazakerley Hospital by removing the present small-pox beds to a new building. These beds will become available for tuberculosis patients.

Wigan Medical Society.

This society held their biennial dinner on Dec. 11th, under the presidency of Dr. J. T. Shirlaw. Over 30 members and guests spent a very pleasant evening together. The guests included Dr. H. Briggs, Mr. W. Thelwall Thomas, Dr. J. Hay, Dr. A. G. Gullan, Dr. Forbes (representing the Liverpool Medical Institution), and Mr. A. A. W. Merrick (representing the St. Helens Medical Society).

Dec. 16th.

SCOTLAND.

Medical Treatment in Scottish Schools.

REGULATIONS under which grants in respect of the medical treatment of necessitous school children during the period extending from Feb. 1st to Dec. 31st, 1914, will be made by the department were recently issued by the Scotch Education Department. It is pointed out that the treatment contemplated does not extend to the provision of medical attendance in cases of accident or of a casual or serious illness, nor does it extend to the provision of education and maintenance on behalf of blind or deaf-mute children, or those defective mentally, or epileptic. It would, however, cover cases of defective vision, defective teeth, and similar ailments which may be said to affect the general health or, at any rate, the educative capacity of the child. The department also require that, except in circumstances of very special difficulty, all treatment shall be given by fully qualified specialists or general practitioners, according to need. The department will also be prepared to consider the question of making grants for open-air schools for children suffering from tuberculosis or other ailment requiring open-air treatment.

Indian Students at Edinburgh Medical School.

At a public meeting held in Edinburgh recently, which was attended by over a hundred Indian students, hostile sentiments were voiced towards the newly formed subcommittee of the Advisory Council, which is to inquire into "any and all grievances which Indian students may have to bring forward, whether against educational or any other institutions of this country (including the Bureau for Information at 21, Cromwell-road, London)." The following resolution was carried by the meeting:—

That this meeting of Indian students in Edinburgh, finding that Indian students have no special grievances apart from those which they may have as members of the University equally with students of other nationalities, resolves that no useful purpose would be served by placing such grievances before the subcommittee of the Advisory Council appointed by the India Office; and are convinced that their interests will receive in the future, as they have done in the past, the sympathetic attention of the University and other educational authorities.

Tuberculous Patients in Edinburgh Poorhouses.

At a statutory meeting of the parish council held on Dec. 8th the question of the treatment of patients with pulmonary tuberculosis in their wards was dealt with, and a report dealing with this subject during a period of the last three years was read. The advisability of compulsory retention until non-infectivity was established was strongly advocated, and the small percentage of cures—only 1 per cent.—was explained by the fact that practically all the cases were advanced ones, and that many of these were in and out of the wards over long periods, one patient being admitted as often as 43 times. A certain number of the beds available for phthisical cases at the Craiglockart poorhouse are now to be under the charge of the public health authorities, and thereby their available beds for earlier cases will no doubt be considerably augmented.

Local Government Board and Typhoid Fever in Aberdeen.

At a recent meeting of the public health committee of the Aberdeen town council a letter was read from the Local Government Board stating that the Board had had under consideration the report of Professor Matthew Hay, medical officer of health, on the outbreak of typhoid fever in the city of Aberdeen during the autumn of 1912. The Board draw the attention of the local authority to Dr. Hay's conclusions, and inquires what action the local authority have taken or what measures they propose to take in order to safeguard the purity of the city's water-supply. The letter was referred to the water committee, who had replied that steps have been taken by the committee with regard to the liming and filtration of the water-supply. The committee also detailed the larger scheme now under review.

Dec. 16th.

IRELAND.

School Dental Clinics.

THE Commissioners of National Education have notified school managers and teachers of the facilities now available for the dental treatment of school children. Schemes for the dental examination and treatment of pupils may now be submitted to the Commissioners, who are empowered to bear half the expense. Though successful schemes are working in a few areas, the Commissioners still have a considerable sum of money at their disposal, and they are anxious that it should be utilised before March 31st, 1914. In the absence of a general scheme of medical inspection, which the Commissioners would like to see established, the care of the teeth of the children is an essential of all school hygiene.

Scarlet Fever in Belfast.

The scarlet fever outbreak here shows no signs of lessening, and on Dec. 11th, it was reported that for the week ended Dec. 6th 84 cases had been notified, which is an increase of 17 on the previous week. At one end of the city a local outbreak of the disease has also occurred, it is said, by milk conveyance. The public are becoming very uneasy as the epidemic continues without abatement, and the public health committee have asked their officials if they can suggest any means to stop it. As a result, two medical men have been appointed to visit the primary schools to examine the children, and already they have detected many mild cases that had not been noticed or reported, some in the stage of desquamation. Another suggestion should be acted upon, and that is to appoint one or two assistant medical officers of health, as it is impossible to expect one officer of health to look after a city with a population estimated at the middle of 1913 as being

396,000. For instance, if there is any suspicion about a dairy being the vehicle by which typhoid or scarlet fever is conveyed, it is useless to send ordinary inspectors to investigate the question. They do their very best, and no doubt collect useful information, but they have not the right knowledge of the behaviour of disease. What is wanted is young medical men with a knowledge of the latest laboratory methods, and who have had practical experience as house physicians in some good fever hospitals. The public of Belfast have a feeling that the public health administration will have to go a little more with the scientific progress of the day, and that it is really no excuse for the existence of a gradually increasing epidemic of four years' duration to say, "We can do nothing; we are only like other cities in this respect."

Sanatorium Benefit in Ulster.

The Sanatorium Committee of County Down had almost completed arrangements to have a sanatorium erected at Killynether, a beautiful situation about three miles from Comber, but the plan has fallen through. The County Tyrone county council have adopted a scheme by which two convalescent homes and dispensaries are to be erected in towns in the county, each to contain a dispensary, waiting-room, and eight beds, with accommodation for staff, at an approximate cost of £800; also the provision of six sleeping shelters to cost £25 each. It is also suggested that a surgeon-dentist be appointed and that tuberculosis dispensaries be opened in Strabane, Omagh, Dungannon, Cookstown, and Clogher. It is left optional to the Sanatorium Committee to select a suitable site for a sanatorium to contain 20 beds. It is roughly estimated that the expenses of this scheme will be £2886 annually.

Dec. 15th.

PARIS.

Decrease of Vaccination in France.

THE chief of the vaccination institute at the Académie de Médecine de Paris, as the result of an examination of the French vaccination statistics for some years past, finds that vaccination is decreasing in many of the departments. The legally prescribed revaccinations are but little attended to save when there occurs an occasional epidemic; but there is a remarkable diminution in the primary vaccinations in infancy which the law demands, notwithstanding the numerous affairs of life in which citizens of either sex cannot escape the demand for the production of a vaccination certificate—such as entry to private or public schools, service in the army, admission to any administrative office, and so forth. Nevertheless, many folks manage to escape it, rather through negligence than from any considered antivaccination ideas, for there are few antivaccinators in France. Notwithstanding that every child is required by law to be vaccinated in infancy numbers of conscripts join their regiments who have never been vaccinated. They are at once vaccinated, of course, by order of the medical officer. M. Camus's statistics show a lessened vaccination rate throughout France. Primary vaccination, though increasing for the large cities like Paris, Lyons, Lille, Bordeaux, and Marseilles, is diminishing in 60 departments. Last year in only 38 departments was there a diminution as compared with the preceding year. It is true that the number of cases of variola continues to diminish yearly, the reason being doubtless that in consequence of the severe epidemic of 1907 almost the entire population got vaccinated in a panic, the acquired immunity from which still persists. But it is to be feared that if any great movement of the population should take place, as, for instance, a military mobilisation, the disease would reappear. M. Camus calls on the Government, therefore, to keep closer watch on the regular and continued administration of the law.

An Uncommon Intestinal Parasite.

Professor Blanchard has reported to the Académie de Médecine the sixth case noted in France (the sixty-seventh in scientific literature) of infection by the dipylidium caninum. The present case occurred in an infant 7½ months old. The organism is parasitic in the dog, from which it is conveyed by fleas, through milk and other foods which they frequently contaminate. This kind of tænia, which seems to cause infection more frequently now than formerly, gives rise to an ensemble of symptoms among which epileptiform attacks predominate.

Alopecia of Dental Causation.

Dr. Jacquet has long been a believer that alopecia is a trophoneurosis of purely reflex and non-parasitic origin, and has reported many observations in which when the alopecia coincided with dental lesions the cure of the latter has been accompanied by the disappearance of the former. He has now added a very curious case which possesses almost the weight of a physiological experiment. A lady had periodontitis. The tooth was loose in its socket, and each time it was moved she immediately felt a sharp pain in the left parietal region, always at the same spot. One day she had the tooth removed, and almost immediately a patch of alopecia appeared exactly at the spot where the pain used to manifest itself. This patch did not last long, but underwent a spontaneous cure.

A New Culture Medium for the Gonococcus.

M. Auguste Lumière and M. Jean Chevrotier have brought before the Académie des Sciences a new culture medium for the gonococcus. It consists of 6 grammes of albumin in a litre of beer wort. This is put into the autoclave at a temperature of 115° C., filtered, rendered alkaline, and sterilised afresh at 110° C. for 10 minutes. It is improved by the addition of 1½ c.c. of horse or ass serum to 15 c.c. of wort, though this is not essential. With this liquid it has been possible to obtain cultures from pus taken at the hospital in the morning and left for some eight hours at ordinary temperatures, then sown without reheating. The culture shows itself fertile next day, after a night passed in the *étuve*. This discovery is interesting in view of the production of antigonococcic vaccines. The fact from which this process was developed—viz., that beer favours the development of the gonococcus—is in line with the well-known fact that the ingestion of beer in a person infected with the gonococcus increases the intensity of the urethritis.

Death of Dr. Empis.

Dr. Empis, to whom reference was made in this column last week, has just died. He was the *doyen* of the Académie de Médecine. He had been *médecin des hôpitaux* of Paris, professor *agrégé* of the Faculty of Medicine, and President of the Academy in 1883. His name is associated with some remarkable studies on acute miliary tuberculosis, of which he has left a classical description.

Dec. 15th.

Obituary.

SYDNEY JONES, M.B. LOND., F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL; LATE MEMBER OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE have already recorded the death of Mr. Sydney Jones, which took place on the morning of Dec. 7th, in his eighty-third year. For some years he had given up the practice of his profession and lived in comparative retirement, seldom visiting away from his own circle of relations. As increasing years brought various ailments he turned to his old pupil, Dr. Edwin Smith, for help, which was most kindly given.

Sydney Jones, the eighth son of Mr. Robert Jones, of Walworth, was educated at Stanmore and King's College, from which places he matriculated at the London University. He was then apprenticed, in accordance with the custom of the day, to Mr. Bristowe, of Camberwell, father of Dr. John Syer Bristowe, the well-known physician to St. Thomas's Hospital, and author of the famous text-book. In due course he entered as a student at St. Thomas's Hospital, where he gained many of the prizes open to competition by the students. In the year 1853 he took the diploma of Member of the Royal College of Surgeons of England, and became a Licentiate of the Society of Apothecaries. In 1856 he became Bachelor of Medicine of the University of London and a Fellow of the Royal College of Surgeons. He spent some time in Paris studying surgery in the Hôtel Dieu and Lariboisière Hospitals, and became an assistant surgeon to St. Thomas's Hospital in 1860, with charge also of the ophthalmic department. He was also appointed lecturer on descriptive and surgical anatomy and ophthalmic surgery. In January, 1871, he was appointed full surgeon to the hospital, with charge of beds, and a joint lecturer on systematic surgery. By this time he had made a mark as an operating surgeon, and in 1883 he was chosen by the Fellows as a member of the Council of the Royal College of Surgeons and was also appointed an examiner in surgery to the Royal College of Physicians of London. At the close of 20 years' service as surgeon to St. Thomas's Hospital he retired with the rank of consulting surgeon. Having now more leisure he accepted the position of examiner to the University of Glasgow and held it for the usual term.

SYDNEY JONES, M.B. LOND., F.R.C.S ENG.,
CONSULTING SURGEON TO ST. THOMAS'S HOSPITAL.
(From a photograph by Ball, Wilton-road, S.W.)

Sydney Jones was essentially a man of practice and not theory; he was not what is called "an original investigator," but readily adopted any method of wound treatment that appeared to possess advantage over previous procedures. In addition he accepted and practised any new manner of operative interference which offered a prospect of a better result, and we published many cases in our columns, chiefly in the Mirror of Hospital Practice, which showed that he was well in the forefront in all changes which were taking place in the general practice of surgery. He was operating largely at a time when rapidity was a necessity for success as a surgeon; and he was quick and brilliant as well as sound in such happy combination that many accounted him the best operator in London of his day. There were several operations which were considered in the "seventies" and "eighties" of the last century as the highest tests of an operator, and to see Sydney Jones perform a lateral lithotomy, remove a foot by Syme's method, or excise the upper jaw, surgeons would travel for long distances, and the auditorium of the operation theatre was sure to be crowded. His extensive knowledge of anatomy stood him in good stead through life, and when talking over the prospects of the success of a new operation or a supposed improvement in an old one his criticism was very sound. He did not contribute largely to the literature of the profession, preferring to write practical comments on cases, which were always very instructive, to placing ideas before his contemporaries which he thought might be of doubtful value. He made, however, several contributions to the annual volume of the reports of St. Thomas's Hospital; probably the papers which attracted most attention were those dealing with the treatment of diseased joints by excision. As curator of the museum of St. Thomas's Hospital he compiled a descriptive catalogue which was published in three volumes, the last being issued in 1859. At this time one other hospital only—namely, St. Bartholomew's—had published a catalogue of its museum pathological preparations, and it was owing to the undoubted value of Sydney Jones's work that the governors of St. Thomas's Hospital ordered the catalogue to be published. The task occupied three years, and in the preface to the catalogue it was stated that the entire collection required revision, that one-third of the specimens had to be described, and that many of the descriptions in the original manuscript required alteration or correction.

There could be little doubt of the excellent impression which his careful methods of investigation and thorough treatment of cases made upon the students under him in the wards, whilst his

impressive delivery and methodical arrangements of lectures, both systematic and clinical, rendered him popular in both school and hospital. In addition to the appointments at St. Thomas's Hospital Mr. Sydney Jones was consulting surgeon to the London Throat Hospital, the Surrey Dispensary, the Royal South London Dispensary, and to the Luton, Beckenham, and Hatfield Broad Oak cottage hospitals.

Mr. Sydney Jones married Miss Mary Morris, and had five children, of whom two sons, Dr. Sydney Harold Jones and Mr. Bevington Sydney Jones, both in the medical profession, and one daughter, Mrs. Pietersen, survive him. Many old St. Thomas's men will recall with gratitude the hospitable reception which was given them when visiting George-street, where most of Mr. Jones's professional life was passed.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. E. Schar, director of the Pharmaceutical Institute of the University of Strasburg.—Dr. G. J. Kleinschmidt, professor of anatomy in the Marquette University, Milwaukee.—Dr. W. Posthauer, formerly adjunct professor of physiology in the Milwaukee Medical College.—Dr. Manuel Brea, gynæcological physician to the Rivadavia Hospital, Buenos Aires, aged 34.—Baron de Bonet, rector of the University of Barcelona, who was eminent both as a clinical physician and an operating gynæcologist. He is stated to have been the first Spanish operator to perform ovariotomy.—Dr. J. de Boeck, professor of psychiatry and forensic medicine in the University of Brussels.—Dr. Alessandro Cugini, formerly professor of forensic medicine in the University of Parma.—Dr. Zambaco Pasha, of Constantinople, associate member of the Paris Academy of Medicine.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Medical Officer of Health for Montreal.

Dr. Louis Laberge, on account of weakened health subsequent to a carriage accident, has tendered his resignation of the position of medical officer of health for Montreal. Dr. Laberge first entered that city's employ in 1878 as vaccination officer, and became head of the medical department seven years later. He has held the latter position for 28 years. The name of Dr. J. E. Laberge, who has been connected with the health department for 20 years, is mentioned for the position.

Montreal Maternity Hospital.

For the hospital year ending Sept. 30th, 1913, the Montreal Maternity Hospital attended to 1243 patients. This is an increase of 250 patients over the previous year. The patients represent 25 nationalities, Canadians leading with 475. In the outdoor department 223 patients were treated. The staff of nurses numbers 21.

Infant Mortality in Montreal.

In a population of 568,000 in 1910 Montreal had 5534 deaths in infants, while Toronto for the same year in a population of 410,000 had 1420 infant deaths. In 1911 a like comparison existed, the figures being 5355 and 1442 respectively. In 1912 Montreal shows a reduction to 4835 and Toronto an increase to 1584. The rate per 1000 of population in Montreal is 9·2 and in Toronto 3·6. Up to August 15th of the present year 4172 infant deaths had occurred in Montreal. The infant mortality in Montreal is more than double that of any other American city. New York, with over 5,300,000 population, has an average of a little more than two infant deaths to every 1000 inhabitants, and Chicago, with its enormous slum areas, has practically the same rate as New York.

New Hospitals for Toronto.

By-laws will be submitted to the ratepayers of Toronto at the municipal elections on Jan. 1st, 1914, to authorise the city council to borrow $250,000 each for grants to two new hospitals to serve the east and west ends of the city. Toronto requires in hospital accommodation about 500 extra beds. The grants will be conditional upon each hospital promotion association first securing by private subscription $250,000 in cash; and the money will be paid by the city as fast as the additional $500,000 is collected, which will mean $1,000,000 for these two prospective institutions.

Cancer in Ontario.

Cancer claimed 176 more deaths in Ontario in 1912 than in 1911. The total deaths each year since 1903 in Ontario is as follows: 1156, 1253, 1224, 1411, 1329, 1348, 1597, 1602, 1778.

Tuberculosis in Ontario.

The decrease in the deaths from tuberculosis in Ontario in 1912 was 103, the total number of deaths from this cause in 1912 being 2250. Just 7 per cent. of the total number of deaths throughout the province was due to tuberculosis. By ages the heaviest death-rate occurs in the twenties. Over 28 per cent. of all deaths from tuberculosis occurred between 20–29 years. That the anti-tuberculosis campaign in Ontario is bearing good fruit is seen in the following figures: 1908, 2511; 1909, 2380; 1910, 2291; 1911, 2353; 1912, 2250. The disease in Ontario does not discriminate to any great extent between the sexes, in 1912 1168 sufferers being males and 1082 females. There is seen some slight difference in the abdominal form of the disease, for in the total for the five years 46·5 per cent. were males and 53·5 per cent. females.

Medical Inspection of Schools in British Columbia.

The second annual report on the medical inspection of public schools in British Columbia for the year ending June 30th has just been issued. British Columbia, according to the special committee on medical inspection of the Canadian Medical Association, is further advanced in this work than any other province in the Dominion of Canada. The work is done under the direction and supervision of the provincial board of health. The report shows that 20 per cent. of the school children of that province reveal some sign of tuberculosis. A report on 29,774 children shows that 16,774 are not vaccinated.

Dec. 3rd.

DONATIONS AND BEQUESTS.—Dr. John Moore Walker, of Edgbaston, formerly medical officer to the Cheltenham Provident Dispensary, has left the residue of his property, amounting to over £30,000, to St. Bartholomew's Hospital, London.—The Royal Victoria and West Hants Hospital will receive £1000 under the will of the late Mr. W. F. Goodliffe.—By the will of the late Miss Elizabeth Maria Hull, of Great Yarmouth, who left estate of the gross value of £37,021, of which £34,418 is net personalty, the testatrix bequeathed, after making several large bequests, the residue of her estate in equal shares to the Brompton Cancer Hospital, the Free Homes for the Dying, Clapham Common, the Royal Eye Hospital, Southwark, the Infirmary for Consumption and Diseases of the Chest and Throat, Margaret-street, Cavendish-square, W., the Hospital of St. Francis of Assisi, and the Poplar Hospital for Accidents.

Correspondence.

"Audi alteram partem."

THE GOVERNMENT OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—The fact is unquestionable that "College politics" have for many years fallen to a very low ebb, despite the annual effervescence at the meeting of the Fellows and Members. Indeed, this term to many in the present day must be almost unknown. And yet 25 years and more ago the scenes which took place at the College, wholly arising from College politics, showed the intense seriousness of those who took part in them. The Fellows as well as the Members were then demanding concessions from the Council. To further the reforms promoted by the Fellows the "Association of Fellows" came into being; its heraldic device was based upon the aphorism "keep pegging away." The Association pegged away to some purpose, as some Fellows, still alive, among its active committee, can bear testimony, among whom may be mentioned Sir John Tweedy, Sir W. J. Collins, Mr. J. Vincent Bell (Rochester), Mr. W. Bruce Clarke, and Mr. A. W. Mayo Robson. We had an excellent president in the late Mr. George Pollock, an ardent hard-working vice-president in the late Mr. Timothy Holmes, and an able and strenuous fighter in the late Mr. Walter Rivington. My duties as honorary secretary merely consisted in summoning the meetings and recording the proceedings. A committee meeting was summoned on an average once a month, in addition an annual general meeting was held, and on occasions an annual dinner. After each meeting a full report of the proceedings was promptly dispatched to the medical journals. At special times a leading article, of course uninspired, would appear in our favour in the press, thus further showing our vitality and evincing our progress. The power and influence of these organising efforts were emphasised at the annual elections of members to the Council.

The Association always made a point of nominating a candidate or candidates out of their numbers. At first the success of these nominations was not conspicuous. Later, however, upon one occasion no fewer than four Fellows whom we supported, all pledged to carry the views of the Association into the Council, were elected. A flutter then took place among those who were opposed to us. We were becoming too strong; our strength was held to be detrimental to the interests of the College. But that was not the real reason for the compliment being paid us by our opponents of founding a rival agency, known as the "Society of Fellows." To pursue, however, the subsequent history of this reform movement is here unnecessary. The main purpose of these remarks is to suggest that if the Members unitedly desire to achieve the objects for which they are now aiming they must become efficiently organised, display an active and continuous vitality in their movement, seek to enlist the services of prominent Fellows willing to undertake their cause, cease the policy of perpetual recrimination against the Council, always so impolitic, and act constitutionally by employing all their efforts among the Fellows to secure the return of candidates pledged to support their views at the annual election to the Council. Even one Members' candidate upon the Council would be expected to have some leavening effect. Meanwhile there remains in front of the Members question an obstruction still as unnegotiable as when it first came into being—namely, the result of the trial, Steele *v.* Savory.—I am, Sir, yours faithfully,

London, W., Dec. 12th, 1913. PERCY DUNN.

THE MEDICO-PSYCHOLOGICAL CLINIC.

To the Editor of THE LANCET.

SIR,—Much publicity has been given to a meeting which was lately held in a hall lent by University College—and for which the College was therefore in no way responsible—to consider a proposal to found a medico-psychological clinic. But the press reports of this meeting have been almost monopolised by detailed accounts of the speech of its chairman, Lord Sandwich. His speech cannot be taken as expressing the views of those really responsible for the project. It consisted chiefly in the description of cures which he claimed to have effected himself by the exercise of some, apparently, occult power. Now the declared object of the clinic was to "bring about a practical alliance between general psychology and psychotherapy." The medical staff have already (in a letter to the two leading medical journals) dissociated themselves from this speech. Having been invited to represent the "general psychology" of the clinic, I should like unreservedly to join in this dissociation.

The notion of the clinic was started by some medical practitioners who, working with myself, realised the great change that is coming over psychology. Formerly it was little more than an occasional hobby of leisure hours. At the present moment there are thousands of enthusiastic workers all over the world giving their lives to psychology as a profession, accurately experimenting with the mind in the laboratories, minutely observing it in hospitals and asylums, making patient records in the nursery and the schoolroom, scouring the earth for its least civilised manifestations, and illuminating it by elaborate study of the conduct of lower animals and even of plants. Concomitantly, there has been evolved an elaborate technique of procedure and apparatus. The aim of all this is the gradual ascertainment of mental law, and the corresponding control of mental event. Just as physical science has taught us to build, to mine, to telegraph, and to fly, so too psychic science is beginning to show us how to train up the growing intellect, emotions, and will, how to diagnose their condition, to maintain them in health, and to heal them when sick. Occultism is not only alien to the spirit of the proposed clinic; it is in direct contradiction of it.—I am, Sir, yours faithfully,

C. SPEARMAN,
Grote Professor of Mind and Logic, University of London, University College.

Dec. 10th, 1913.

RANGE OF FLIGHT OF MUSCA DOMESTICA.

To the Editor of THE LANCET.

SIR,—Mr. Paul B. Roth in THE LANCET of Dec. 6th hopes I may be able to afford some evidence as to the range of flight of Stomoxys calcitrans. I regret I am unable to do so. Stomoxys is only rarely found indoors; it is essentially an outdoor fly. I have twice been stung by this fly out of doors. Occasionally a specimen may be found indoors, but generally at the window trying to get out. I once

observed a considerable number sunning themselves on seats and on a table out of doors at a country inn. As regards poliomyelitis, the majority of sufferers are of tender age. Such cases as have come under my observation have generally had a history of direct or indirect infection through a probable "carrier" coming from an infected area (see annotation in THE LANCET of Dec. 23rd, 1911).

It is clearly quite possible that Rosenau's suggestion of infection conveyed by stomoxys, which has been supported by Mr. Roth and others, may account for some cases, but we should be able to obtain a history of fly-bite in at least some of these cases—for the awl-like proboscis of stomoxys inflicts a sharper sting than that of the mosquito, as I can testify from personal experience of both. It may possibly be considered as evidence in favour of this theory that the majority of cases of epidemic poliomyelitis, which have come under my observation, occurred in a district not many miles from a place where I was stung by a stomoxys some five or six years ago. Generally, flies were numerous at the time of the epidemic in 1911, but there are no records as to whether stomoxys was noted among them, nor was there any history of bites volunteered in any of the cases.

I am, Sir, yours faithfully,

The Shirehouse, Norwich, Dec. 15th, 1913. J. T. C. NASH.

DATES IN PHYSIOLOGY.

To the Editor of THE LANCET.

SIR,—I have to thank your reviewer for the kindly notice of the new edition of my "Handbook of Physiology" which appeared in THE LANCET of Dec. 13th. I am always grateful for suggestions for improvement, and some of those made by your reviewer I hope to avail myself of in future editions. The sentence regarding the importance of inserting a few dates of epoch-marking discoveries in physiology I fully agree with. But your reviewer seems to imply that all such dates are omitted in my last edition, except the comparatively unimportant one of the period of Erasistratus. A more careful perusal of the book will show your reviewer that this is not the case. Dates are given in reference to the work of Harvey, Haller, Wharton Jones, Stephen Hales, Henle, Claude Bernard, and many others of the past. Carl Ludwig and Marey, it is true, are undated, but this applies also to the majority of living physiologists or to those who have also recently died, and there are many reasons for such omissions. The very omission tacitly implies that their work has been carried out during comparatively recent times.

I am, Sir, yours faithfully,

W. D. HALLIBURTON.

King's College, London, Dec. 13th, 1913.

CANCER AND SECONDARY RAYS FROM CALCIUM PHOSPHATE.

To the Editor of THE LANCET.

SIR,—I have accumulated a considerable amount of evidence to the effect that, where cancer has been cured by radium, the effect has been due to secondary radiation from one of the constituents of bone material. The indications are that the constituent is either calcium or phosphorus. Of course, the proper way to attack the problem would be to determine what wave length of X rays is emitted from bone material when exposed to gamma rays from radium, and then to determine what kind of anti-cathode and what hardness of X ray will produce the same secondary radiation. At present I fear that this cannot be done, but by embedding a piece of bone material or calcium phosphate in a cancer and exposing it to a pencil of X rays from a tube with uranium anti-cathode and of the proper degree of hardness I would anticipate much more favourable and consistent results than those obtained from radium.

I am, Sir, yours faithfully,

REGINALD A. FESSENDEN.

Brookline, Mass., Dec. 1st, 1913.

MEDICAL INSPECTION OF PARSI SCHOOL CHILDREN OF THE BOMBAY PRESIDENCY.

To the Editor of THE LANCET.

SIR,—In an annotation of August 16th last on the subject of School Medical Inspection in India THE LANCET was good enough to make a reference to my paper on Parsi Education and Parsi Health, read before the third Zoroastrian Conference. It will therefore be opportune to describe here what followed. The Zoroastrian Conference, which is the leading association looking after the welfare of the Parsi community, passed a resolution at the same sessions during which the paper was read, requesting its standing committee to formulate and enforce a practical scheme of medical inspection, supervision, and treatment of all Parsi school children of the Bombay Presidency. Accordingly, the standing committee appointed a joint committee of leading Parsi educationists, headmasters of schools, and qualified medical men to do what was needful. To this committee I submitted a complete scheme of medical inspection, supervision, and treatment. The scheme was approved and adopted by the joint committee, and I was selected as its medical secretary to put it into working order. Subsequently, at the invitation of the committee more than 30 Parsi doctors, among whom were consultants, specialists, and general practitioners, volunteered their free services at great personal sacrifice for the purposes of medical inspection. So that we have by this time been enabled to complete the medical examination of Parsi pupils of more than half a dozen schools. Our plan is as follows. A week before the inspection our office informs the head-masters of the date on which the pupils are to be examined, and requests them to prepare lists of all Parsi children attending their schools and to forward to the parents of the children a notice explaining the practice and purpose of medical inspection, and a circular for describing the family and the previous history of the children to be filled in by either the parents themselves or their family physicians. The circulars are returnable to this office within four days. Two days previously to the actual inspection a card is sent to the parents inviting them to be present at the time of inspection noted on the card.

The inspection is held on the school premises during school hours, in the presence of one or more class teachers, as well as of the parents of children who may have attended for the occasion. Each child is then successively examined by an eye, ear, throat, and nose specialist, a dentist, and a general examiner, to whose lot falls the examination of all the systems left over by the specialists. The results of these separate examinations are inserted on four different sets of forms issued by this office. If there are any cases requiring further

investigation they are referred to the consultants, and any special cases of urinary or skin diseases are referred to the urologist and the dermatologist. Each child is thus thoroughly examined by four or more fully qualified doctors. In every primary, middle, and secondary school, male and female, all Parsi pupils from the infant to the highest classes have thus the benefit of thorough medical inspection.

As to the treatment of those found suffering from any defect or disease, our office sends advice cards to parents informing them of the results of the examination and advising them to put their children under the treatment of their family physicians. If parents are too poor to afford private medical treatment they are recommended to apply for treatment at one of the Parsi charitable institutions for relief of the indigent and sick poor. We hope in the near future to establish a Parsi school clinic, which would facilitate the following-up and treatment of the suffering children.

As to the feeding of the necessitous children, arrangements have already been made by the authorities of some of our Parsi schools to provide good meals during the day and thus enable the children to profit fully by the education given in their schools. It is expected that other schools will copy their excellent example and look after the starving children. When the Parsi school clinic is established we hope to coördinate the work of medical inspection, following-up, and treatment of the suffering children, as well as the feeding of the necessitous.

This is only the first step in our complete scheme of communal welfare of our school children, and we hope in the near future to complete the scheme by taking the necessary successive steps as circumstances permit. In this task we have the full sympathy and support of our enlightened community, and particularly of the parents of the school children as well as of the teachers, to whose willing help we are much indebted for the serviceable working of our scheme.

I am, Sir, yours faithfully,

K. K. DADACHANJI,
Medical Secretary, the Z. C. Medical Inspection of Parsi School Children of the Bombay Presidency.

Bombay, Nov. 27th, 1913.

THE EBBW VALE WORKMEN'S MEDICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—Some three or four weeks ago the *British Medical Journal* published a statement to the effect that the Ebbw Vale Workmen's Medical Society—in common with those of Tredegar, Rhymney, and Aberdare—retained the old salaried system and gave no free choice of doctor. What obtains in these places I am not prepared to state, but I note that in your issue of last week you have apparently fallen into the same error as regards Ebbw Vale. Your contemporary has twice been given the opportunity of correcting its statement, which is opposed to the true facts of the case, but has failed to do so. I therefore ask you in fair play to remove the false impression created by your leading article.

The Ebbw Vale Medical Society has recognised to the fullest extent the principle of "free choice of doctor"; it pays no salaries—the remuneration of the medical man depends entirely on the number of capitation fees from the number of payees "signing on" for him; there are no districts; the doctors are in no sense "whole-time" men—they are allowed private practice, to have patients on the "public panel," and to hold any other posts they may be able to obtain. The society maintains a 22 bed hospital with a modern equipment for its payees and their dependents, and there is no "touting" in the district, as there is nothing to be gained by such a proceeding, as with one or two exceptions all the medical men in general practice—members of the British Medical Association and others—are on the panel of the society.

I am not on the panel myself and therefore do not feel at liberty to disclose the actual financial terms existing between the medical men and the society, but I believe that, if not the best in the United Kingdom, they are second to none in liberality.

I am, Sir, yours faithfully,

HUGH NEVILLE TAYLOR, M.A. Cantab., M.A., M.D. Dub., F.R.C.S.E. Edin.,
Surgeon, Ebbw Vale Hospital.

Ebbw Vale, Dec. 15th, 1913.

*** Our correspondent must be referring to a sentence in one of the articles by our Special Commissioner, and not to any leading article. We wish that Dr. Taylor had felt able to publish the exact conditions of service at Ebbw Vale.—ED. L.

INTESTINAL "KINKS."

To the Editor of THE LANCET.

SIR,—Assuming a kink of the intestine to be an acute bend or angulation caused by adhesions or bands, I ask leave to submit the following questions to my colleagues: 1. Does a kink produce symptoms by causing obstruction to the passage of the bowel contents? 2. If a kink does not cause symptoms of obstruction, what symptoms may it produce? 3. If a portion of bowel is chronically obstructed, does the bowel above the obstruction become either hypertrophied or dilated, or both? 4. In the absence of both hypertrophy and dilatation of the bowel proximal to the kink, what signs would indicate that the kink is causing obstructive or other symptoms? 5. Is the presence of a kink in a portion of intestine drawn up to or beyond an incision in the abdominal wall proof that a kink exists when the bowel lies within the abdomen?

I am, Sir, yours faithfully,

Plymouth, Dec. 9th, 1913. C. HAMILTON WHITEFORD.

FOREIGN UNIVERSITY INTELLIGENCE.—*Angiers:* Dr. Thibault, professor of internal pathology, has been appointed Professor of Clinical Medicine, in succession to the late Dr. Jagot. Dr. Denechau has been appointed to the chair of Internal Pathology. Dr. Vinsonneau has been appointed to the chair of Clinical Ophthamology, in succession to the late Dr. Motais.—*Berlin:* Dr. Max Stickel has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Brunswick:* Dr. Walter H. Schultze, prosector to the Grand Ducal Hospital and *dozent* of hygiene and bacteriology in the Technical School, has been granted the title of Professor.—*Budapest:* Dr. A. von Lichtenberg, of Strasburg, has been offered the post of Chief Medical Officer of the General Policlinic.—*Buenos Aires:* A new hospital has just been opened by the Spanish Benevolent Society for both poor and well-to-do Spaniards, the Hospital y Asilo de Temperley; it is splendidly fitted up with baths and all modern improvements. Dr. Alvaro Newton has been appointed by the municipal authority Director of the Hospital Durand.—*Freiburg:* Dr. Curt Ziegler, *privat-docent* of medicine, has been offered an Extraordinary Professorship of Medicine with the post of Director of the University Medical Clinic.—*Giessen:* Dr. A. Brüggemann has been recognised as *privat-docent* of Otology and Laryngology.—*Greifswald:* Dr. P. Morawitz, extraordinary professor in Freiburg, has been appointed to the chair of Clinical Medicine, in succession to Dr. Steyrer, who is going to Innsbruck.

THE NATIONAL INSURANCE ACT.

CLAUSE 2 (ii.).

AT a recent meeting of the Cardiff Insurance Committee the Local Medical Committee submitted an amendment to the clause in the new model agreement which seeks to prohibit the practitioner from accepting any fee or other remuneration in respect of treatment which he is required to give to an insured person under the agreement. The amendment, which would have prohibited the demand, but not the acceptance, of an extra fee, was lost after a discussion in which reference was made by a speaker to the question as one of "tipping the doctor." The offensiveness of this phrase was pointed out by the Lord Mayor, and the reasonableness of the amendment, from the point of view of more well-to-do patients, as well as of their medical attendants, was dwelt upon by more than one speaker. In Middlesex amendment of the clause has been sanctioned by the Insurance Commissioners, so that there is added to it (the word "accept" being retained)—

But nothing in this agreement shall be construed as prohibiting the acceptance by the practitioner from an insured person of such fees as may have been agreed between them in writing as a condition of the acceptance by the practitioner of the insured person where the places of residence of the insured person and the practitioner are so situated that access between them is by reason of distance or otherwise difficult or inconvenient, and where there is another practitioner upon the panel by whom the insured person might have been accepted, or to whom he might have been assigned, and whose residence is nearer to that of the insured person or is less inconvenient of access.

The intention of this would appear to be to prevent the medical practitioner where he is free from competition from taking advantage of his position, while according a limited freedom of choice in the matter to the patient. The Middlesex Insurance Committee has also agreed to make a minute that "the phrase 'accept any fee or other remuneration' does not include a present or a gift made by an insured person to a doctor.
Cheshire resolutions of the Medical Ben " In committee adopted by the Insurance Committee include one:—

That the subcommittee consider it undesirable that any alteration should be made in the wording of Clause 2 (ii.).

At Birmingham a subcommittee of the statutory Medical Committee has recommended that after the word "remuneration" should be inserted the words "from the patient." At Ipswich a discussion took place at a meeting of the Insurance Committee, but a proposed amendment of the clause having for its object the substitution of "demand" for "accept" was lost by a considerable majority. The attitude of the Commissioners on the subject in opposition to any alteration was referred to by a speaker as "adamantine."

THE NATIONAL INSURANCE PRACTITIONERS' ASSOCIATION.

At a general meeting of members of the National Insurance Practitioners' Association, held in the Caxton Hall on Dec. 12th, a report was presented of a year's hard work. Having been formed for the specific purpose of inducing men to accept service under the National Insurance Act and to look after the interests of those accepting such service, the association, by means of a very energetic campaign, was able to complete the first part of its programme in a little over a month from its formation, for by that time panels were complete in most areas. The association strove energetically for the simplification of the records, and its influence contributed largely to the Amending Act of 1913. Under this Act panel committees are appointed and recognised by statute, and provision is made for financing them. From the fact that strong panel associations are already in existence or are being formed in London and throughout the country, and that steps are being taken to link these up in one central body, it was considered advisable that the National Insurance Practitioners' Association, having completed the work for which it was called into being, should no longer exist as a separate organisation, but that its members should join their various panel associations and support the central body.

NATIONAL MEDICAL GUILD.

The National Medical Guild is holding a meeting of medical practitioners to-day (Friday, Dec. 19th), at 4 P.M., at the Hammersmith Town-hall, to discuss the value of trade unionism for the medical profession. The chair will be taken by Dr. Charles Buttar, president of the Guild. Mr. E. B. Turner will open the discussion in favour of a trade union. Speeches and questions from the audience will be invited, and a resolution will be put to the meeting at 6 o'clock.

THE TEMPTATION TO MALINGER.

A man was fined 40*s*., with the alternative of 14 days' imprisonment, recently for making a false representation for the purpose of obtaining benefit under Part II. of the National Insurance Act, 1911, the representation being in effect a denial that he was receiving sickness benefit when in fact he was drawing it. As the magistrate observed, it might pay the defendant better to be sick than to be unemployed, but it paid him best to be both, so he drew 10*s*. from his society, 7*s*. from the Labour Exchange, and half wages under the Workmen's Compensation Act. It need hardly be pointed out that when the legislature renders idleness so remunerative the task of the medical man, upon whom is cast the duty of distinguishing feigned from real illness, is not likely to be an easy one.

IPSWICH INSURANCE COMMITTEE.

In addition to the question of Clause 2 (ii.) mentioned above, the Ipswich Insurance Committee discussed at a recent meeting, and agreed to, a new tariff for drugs, excluding a proprietary article of which the contents were not publicly disclosed. The committee also considered the conditions subject to which insured persons should make their own arrangements with medical practitioners when permitted to do so. A new scale had been proposed for this to replace an arrangement by which practitioners not on the panel had agreed to treat patients on the same terms as those on the panel. Questions were settled as to the date of commencement and financial details under the new arrangement by which, it was mentioned, non-panel practitioners would charge 3*s*. 6*d*. for special visits instead of 2*s*. 6*d*., and 5*s*. instead of 3*s*. 6*d*. for night visits.

ABERDEEN INSURANCE COMMITTEE: ALLOCATIONS TO PANEL PRACTITIONERS.

At a meeting of the Medical Benefit Subcommittee of the Aberdeen Burgh Health Insurance Committee held on Dec. 8th a letter was read from the Scottish Insurance Commissioners approving of the following recommendations by the subcommittee:—

1. That no doctor with more than 1000 insured persons on his list as on Dec. 1st, 1913, should participate in the allocation.

2. That no doctor with fewer than 10 patients on his list as on Dec. 1st, 1913, should participate in the allocation.

3. That no insured persons should be placed upon a doctor's list whose surgery or residence was over two miles from the patient's home.

4. That insured persons should be allocated as equally as possible amongst the doctors entitled to share in the allocation.

5. That the doctors with the above qualifications, who came on to the panel after Jan. 12th, 1913, should share equally in the allocation, but that the payments should be made only as from the date upon which they joined the panel.

An amendment was moved that the inverse ratio should be adopted instead of the equal division, but ultimately the recommendations above detailed were adopted, and should the City Health Insurance Committee approve, 35 practitioners will receive about 100 additional patients each.

A PROPOSAL AT MANCHESTER.

Mr. E. Lloyd Jones, chairman of the Manchester Insurance Finance Subcommittee, recently addressed a long letter to the *Manchester Guardian* in support of a proposal made by him to administer benefits under the Insurance Acts by engaging medical practitioners as full-time paid servants of the Insurance Committee, to treat 1500 patients each in return for salaries of £400 a year. This, it will be seen, would mean sweating any members of the medical profession willing to be engaged at about 50 per cent. less than would be their due under the capitation system for the same number of patients. The amount saved Mr. Lloyd Jones would devote to employing specialists and nurses. He writes, "I am not concerned so much about what Mr. Lloyd George promised. What I am concerned about is that the insured persons shall get their rights." Certainly what Mr. Lloyd George promised to insured persons (which they presumably regard as their rights) would not be obtained for them by reverting to the kind of terms associated with the evils of club practice. Medical men also will no doubt consider that they, at any rate, are concerned with their own rights under the Insurance Acts, and with the fulfilment of promises made to them by the Chancellor of the Exchequer.

THE Royal Dental Hospital, Leicester-square, has received £5 as a Christmas donation from H.M. the Queen.

THE Metropolitan Asylums Board has appointed Dr. E. B. Sherlock, who has been in the service of the Board for several years, to be medical superintendent of Darenth Industrial Colony, in place of Dr. Arthur Rotherham, who has been appointed a Commissioner under the Mental Deficiency Act, 1913. Dr. J. L. Gordon, assistant medical officer at Caterham Asylum, has been promoted to fill the resulting vacancy of acting medical superintendent at the Fountain Temporary Asylum.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of Council on Dec. 11th, 1913, diplomas of Fellow were conferred upon 28 candidates who successfully passed the final examination which was held on Nov. 20th, 25th, 26th, 27th, 28th, and 29th last, for which 68 candidates presented themselves. The following are the names and schools of the successful candidates:—

Robert Morison Rowe, M.A., B.Ch., M.D. Edin., M.R.C.S., L.R.C.P., Edinburgh University and St. Bartholomew's Hospital; Philip Julius Franklin, M.R.C.S., L.R.C.P., Middlesex and London Hospitals; Thomas Herbert Cecil Benians, M.R.C.S., L.R.C.P., and George Henry Chisnall, M.B., B.S. Lond., M.R.C.S., L.R.C.P., London Hospital; Trevor Berwyn Davies, M.D., B.S. Lond., M.R.C.P., University College Hospital; Mark Bates, B.M., B.Ch. Oxon., M.R.C.S., L.R.C.P., Oxford University and St. Bartholomew's Hospital; Charles William Archer, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Bartholomew's Hospital; Edward Holmes Rainey, M.R.C.S., L.R.C.P., London Hospital; John Lichtenstein Ritchie, M.B., Ch.B. Birm., M.R.C.S., L.R.C.P., Birmingham University; Frank Holt Diggle, M.B., Ch.B. Manch., F.R.C.S. Edin., M.R.C.S., L.R.C.P., Manchester University and St. Bartholomew's Hospital; James Stanley Jobson, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and London Hospital; Stanley Eric Vincent Brown, M.B., Ch.B. New Zealand, M.R.C.S., L.R.C.P., Otago University and London Hospital; Adrian Leonard Moreton, M.B., B.S. Lond., M.R.C.S., L.R.C.P., and Clement Treves Neve, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Robert Anstruther Ramsay, B.C. Cantab., M.R.C.S., L.R.C.P. Cambridge University and St. Bartholomew's Hospital; Edward Gustave Schlesinger, M.B., B.S., B.Sc. Lond., M.R.C.S., L.R.C.P., Guy's Hospital; Norman Duggan, M.B., Ch.B. Vict., M.R.C.S., L.R.C.P., Manchester University and University College Hospital; Wilfrid Archer Sneath, M.B., Ch.B. Manch., M.R.C.S., L.R.C.P., Manchester University and London Hospital; Sidney Bertram Radley, M.B., B.S. Lond., M.B., Ch.B. Manch., M.R.C.S., L.R.C.P., Manchester University and St. Bartholomew's Hospital; Francis Gordon Bell, M.B., Ch.B., M.D Edin., M.R.C.S., L.R.C.P., Edinburgh University; Norman Claudius Lake, M.D., B.S., B.Sc. Lond., M.R.C.S., L.R.C.P., Charing Cross Hospital; John Tertius Morrison, M.B., Ch.B. Edin., M.R.C.S., L.R.C.P., Edinburgh University and Guy's Hospital; Edward Rayner, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and St. Thomas's Hospital; John Smeed Bookless, M.B., B.S. Lond., Guy's Hospital; Alexander Gibson, M.A., M.B., Ch.B. Edin., Edinburgh University; John Gow, M.B., Ch.B. Manch., Manchester University; Ronald Chesney MacQueen, M.B., Ch.B. Edin., Edinburgh University and London Hospital; and Joseph Collingwood Stewart, M.B., M.S. Durb., Durham University.

Licences to practise Dentistry were conferred upon 54 candidates who have passed the requisite examinations and complied with the by-laws:—

Leslie Alabone, Guy's Hospital; Henry John Farrow Alexander, Middlesex and Royal Dental Hospitals; Reginald Hugh Basker, Bristol University; Fritz Ernest Bendix, Middlesex and Royal Dental Hospitals; Caswell Glynne Bowen, Charing Cross and Royal Dental Hospitals; Reginald Gordon Bradley, Allwright Alfred Brown, William Allen Bulleid, and Alfred Fisher Camp, Guy's Hospital; James Percy Cocker, Leeds University; Louis Charles Cohen and Richard Groves Cowell, Guy's Hospital; Frederick Andrew Crane, Middlesex and Royal Dental Hospitals; Walter Alexander Craine, Liverpool University; Edmund Dinsmore, Charing Cross and Royal Dental Hospitals; Cyril Henry Edwards, Guy's Hospital; Percy William Flook, Bristol University; William Trevor Flooks and William Kelsey Fry, M.R.C.S., L.R.C.P., Guy's Hospital; Vivian Arthur Frederick Greenish, Middlesex and Royal Dental Hospitals; Frank Cecil Harrison, Sheffield University and Royal Dental Hospital; Carl Joseph Oldham Jensen, Charing Cross and Royal Dental Hospitals; Edward Eastaugh Johnson, Guy's Hospital; William Sanders Johnstone, Charing Cross and Royal Dental Hospitals; Norman Harold Kettlewell, Middlesex and Royal Dental Hospitals; Sidney McCallin, D.D.S., Chicago and Middlesex Hospital; Percy Scott McFarlane, Guy's Hospital; Wilfred Richard Matthews, Middlesex and Royal Dental Hospitals; Lancelot Turtle Montgomery, Guy's Hospital; Norman Mulliner, Liverpool University; Cyril Henry Oliver and John Stanley Palmer, Guy's Hospital; Haydn Peters, Middlesex and Royal Dental Hospitals; Kingsley Chisman Pitman, Guy's Hospital; Francis Rupert Rice, Middlesex and Royal Dental Hospitals; Reginald Harry Rix, Guy's Hospital; George Herbert Heywood Russell, M.B. Manch., Manchester University; George Vincent Saunders, Guy's Hospital; Sydney Frank Simpson, King's College and Royal Dental Hospitals; Herbert Leslie Smith and Robert Cyril Wilmer Staley, Guy's Hospital; Thomas William Stark, B.A. Lond., Middlesex and Royal Dental Hospitals; Stanley Stevens, Guy's Hospital; Eric Wesley Thomas, Bristol University; Harold Treleaven, Charing Cross and Royal Dental Hospitals; Arthur Bayford Guy Underwood, M.B., B.S. ROYAL SANITARY INSTITUTE.—Colonel Guy Carleton Jones, M.D., Director-General, Medical Service of the Militia of Canada, and Dr. William Robertson, medical officer of health, Leith, have been elected Fellows of the institute; and Dr. W. W. Aylen, Dominion Quarantine Officer, Montreal; Dr. Louis Laberge, medical officer of health, Montreal; Major N. J. C. Rutherford, R.A.M.C.; and Mr. H. G. Waters, medical officer of health, Jamalpur, have been elected members.

Mr. G. L. Eastes ask us to state for the convenience of our readers that the laboratories at 38, New Cavendish-street, London, W., will be closed on Thursday, Friday, and Saturday, of next week, except for the examination of diphtheria swabbings and other very urgent specimens.

ROYAL MEDICAL BENEVOLENT FUND.—At the November meeting of the committee 32 cases were considered and grants amounting to £332 made to 29 of the applicants. Appended is an abstract of the cases relieved:—

Daughter, aged 39, of late M.D. Edin. Has maintained herself as mother's help, &c., but has been strongly advised to take up maternity nursing and requires assistance with the expenses of her training. Voted £10.—Widow, aged 43, of L.R.C.P., L.R.C.S. Edin. Lost her husband a few months ago after an illness lasting several months, and is left quite unprovided for. Five children, three dependent and the two elder only earning a few shillings a week. Voted £10.—Widow, aged 46, of M.R.C.S. Endeavours to support herself by letting lodgings, but cannot quite meet her expenses until her children are self-supporting. Relieved four times, £47. Voted £12.—Daughter, aged 36, of late M.R.C.S. Has a post at a small weekly wage at a jeweller's shop, but thinks that if she can learn typewriting she will be able to improve her position.—Relieved once, £5. Voted £10.—Daughter, aged 84, of late M.D. Glasg. Supported herself for several years by letting lodgings, but is in difficulties owing to the long illness of a sister who recently died. Only income an Old Age Pension. Voted £18.—Daughter, aged 47, of L.R.C.P., L.R.C.S. Glasg. Has an income of £22 a year, and hopes to supplement it by teaching, but requires a rest after nursing her mother (recently deceased) for several months. Voted £5.—Daughter, aged 46, of L.R.C.P., L.R.C.S. Edin. Has been a nurse in an isolation hospital for 12 years, but has broken down in health and is ordered a complete rest. Voted £5.—Widow, aged 47, of L.R.C.P., L.R.C.S. Irel. Is endeavouring to establish a small boarding-house at a seaside town, but has had a bad season and heavy expenses owing to the serious illness of one of her boys who is a foundationer at Epsom College. Voted £12 in 12 instalments.—Daughter, aged 39, of late M.R.C.S. Is well educated and intelligent, but suffers from chronic retinitis which compels her to depend upon her mother whose income is less than £40 a year. Relieved once, £5. Voted £10.—Daughter, aged 54, of late M.R.C.S. No income, and unable to support herself owing to permanent bad health; slight help from a relation. Relieved 4 times, £44. Voted £12.—Widow, aged 53, of L.S.A. Almost blind and deaf, and dependent on a son who only earns 25*s.* a week. Relieved seven times, £104. Voted £18.—Daughters, aged 62 and 54, of late M.R.C.S. No income; endeavour to support themselves by receiving boarders, but find difficulty in obtaining them, and are both in feeble health. Relieved four times, £64. Voted £18.—Widow, aged 76, of M.D. Income less than £1 a week, and asks for a little help towards expenses which are unavoidable on account of ill-health and old age. Relieved eight times, £46. Voted £5.—Daughter, aged 63, of late M.R.C.S. Supplements a small pension from a charitable society by taking boarders, but finds great difficulty in making both ends meet. Relieved twice, £20. Voted £10.—Daughter, aged 68, of late M.R.C.S. Has maintained herself since father's death several years ago by receiving boarders, but now only has one and is constantly in difficulties. Relieved once, £12. Voted £12.—Widow, aged 82, of M.R.C.S. Has a small annuity, but asks for assistance towards unavoidable expenses incurred through an accident. Relieved four times, £35. Voted £5.—Widow, aged 66, of L.R.C.P. Edin. Has a small pension from a City Company, but finds it insufficient for bare necessities, and is in bad health and crippled by rheumatism. Relieved seven times, £48. Voted £12.—Widow, aged 72, of L.R.C.P. Edin. Only income an old age pension; sight failing and health indifferent. Relieved six times, £72. Voted £12.—Widow, aged 68, of M.R.C.S. Supported herself for several years after her husband's death, but was obliged to give up her last post owing to ill-health. Has an annuity of £10 and is allowed the same amount by a friend. Relieved five times, £54. Voted £9.—L.R.C.P., L.R.C.S. Edin. Has been incapacitated for some years by spastic paraplegia, and is dependent on a sister who can ill afford to help. Relieved nine times, £108. Voted £12.—Daughters, aged 61 and 56, of late M.R.C.S. No income; slight help from friends and small earnings by needlework. Relieved nine times, £134. Voted £20.—Widow, aged 76, of L.R.C.P. Edin. Supplements an income of a few shillings a week by taking lodgers. Children unable to help; health failing. Relieved three times, £36. Voted £12.—Daughter, aged 66, of late M.R.C.S. Income £22 a year. Is obliged to ask for assistance owing to increasing infirmities and indifferent health. Relieved five times, £60. Voted £12.—Daughter, aged 59, of late L.S.A. No income, but is at present receiving a few shillings a week from a relation; has always been in bad health. Relieved 14 times, £137. Voted £15.—Daughter, aged 68, of late M.R.C.S. Has a pension of £22 a year, and receives occasional slight assistance from friends; is a permanent invalid and at present unable to leave her room. Relieved seven times, £71. Voted £12.—Widow, aged 55, of L.F.P.S. Glasg. No income, and endeavours to maintain herself by taking boarders. Relieved three times, £30. Voted £10.—Daughter, aged 60, of late M.R.C.S. Has maintained herself for some years, but is now in difficulties which it is hoped will prove temporary. Relieved once, £10. Voted £10.—Daughter, aged 61, of late L.R.C.P. Edin. Is unable to support herself owing to permanent deafness, and is consequently dependent on a sister who is a mental nurse. Relieved eight times, £92. Voted £12.—L.R.C.P., aged 78. Acts as ship's surgeon when able to obtain a post as such, but is at present unemployed. Relieved twice, £24. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

*** The summary of vacant appointments, published weekly in this column, is, equally with other articles, the literary copyright of the Proprietors of THE LANCET.

Births, Marriages, and Deaths.

BIRTHS.

MAYOU.—On Dec. 11th, at New Cavendish- street, London, the wife of M. S. Mayou, F.R.C.S., of a daughter.

ODELL.—On Dec. 14th, at "Ferndale," Torquay, the wife of William Odell, M.D., F.R.C.S., of a son.

MARRIAGES.

CRABB—NEWNHAM.—On Dec. 11th, at Holy Trinity, Dorchester, Robert Lawson Crabb, M.D., B.S.Lond., to Alice Muriel, elder daughter of Mr. and Mrs. H. S. Newnham, of Rodlands, Dorchester.

TATCHELL—FRASER.—On Nov. 29th, at St. Paul's, Westbourne Grove, Percy Tatchell, M.R.C.S., L.R.C.P., to Miriam, youngest daughter of the late James Fraser and of Mrs. Fraser, of Prince Edward Mansions, W., and Craighill, Kessock.

DEATHS.

BROWN.—On Dec. 12th, 1913, at 2, Edge Hill-road, Sheffield, John Henry Brown, M.D., C.M. Edin., M.R.C.S. Eng., late of 14, Burngreave-road. Born Jan. 10th, 1859.

HOLDING.—On Nov. 5th, at Leipsic, John William Carter Holding, L.R.C.P., L.R.C.S. Edin., M.D. Leipsic, of Stutterheim, Cape Colony, eldest son of the late J. C. Holding, J.P., of Lake View, Southsea.

WOODS.—On Dec. 10th, at Dashwood House, Ramsgate, from septic poisoning, Frank Woods, M.R.C.S., L.R.C.P., L.S.A.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A DANGEROUS PRACTICE.

A MEDICAL correspondent, Dr. Alice M. Corthorn, has brought to our notice what we believe is an isolated incident; but even so, the danger of such a practice is sufficiently great to call for notice in our columns. The history related by Dr. Corthorn is that a lady patient recently informed her that an American friend, a layman, had offered to inject a vaccine into her "to increase the resistance of her phagocytes," and had produced a syringe and a phial of vaccine for the purpose. The patient, however, wisely preferred to take qualified medical advice before submitting herself to this treatment. The phial was contained in a box, the lid of which is now before us, and the label reads as follows:—

Streptococcus py. 30,000,000,
Pneumococcus 40,000,000,
Staphylococcus py. Aureus and Albus
each 100,000,000.
One adult dose. Children, from ¼ to ½ this amount.
Given hypodermically at intervals of from 1 to 6 days.
Good until Sept. 7th, 1912.
U.S. License No. 30.
Prepared in the Bacteriological Laboratory of
G. H. Sherman, M.D., Detroit, Mich.
Shake before using.

From the history it would almost appear that these products can be purchased without restriction by lay persons, who in turn may administer them with no knowledge whatever of the indications for or against their use, and without any warning of the dangers involved.

SWAZILAND.

FROM the Blue-book of this South African Protectorate for the year 1912-13 it appears that the total population, as shown by a census taken on May 7th, 1911, was 99,959, composed of 1083 Europeans, 143 coloured persons, and 98,733 natives, as compared with 890 Europeans, 72 coloured persons, and 84,529 natives in 1904. The general health of the community during the year was not as good as usual, especially in the early months of 1913. The prolonged drought and the heat of the early part of the summer were followed by heavy rains. Malarial fever was more severe than usual in the lower-lying portions of the territory, and the mortality was especially high amongst native children. The Government distributes free issues of quinine to natives, but as a rule they prefer their native remedies. A few cases of typhoid fever occurred amongst the European population, but there were no outbreaks of any other contagious disease. Dr. T. S. Dunn, who was acting temporarily as medical officer in the Hlatikulu district, made the discovery that the tick Ornithodorus moubata, which conveys African relapsing fever, is common in Swaziland. No opportunity for investigation of a case has yet offered itself. Syphilis is common amongst the natives. Successful results have been obtained from injections of salvarsan. The climate is healthy, except in the low veld, which is malarial during the rainy season. The average rainfall for the year ended March 31st, 1913, at stations over 3000 ft. altitude, was 39·66 in. on 140 days; under 3000 ft., 32·50 in. on 90 days, the means for the past nine years being 40·02 and 33·11 in. respectively. The mean maximum screen temperature at Mbabane during this period was 73·7° F., while the mean minimum was 51·7°. The highest screen temperature recorded at this station was 94°, while the lowest was 31°. In the middle and low veld the temperatures are considerably higher. The hospital at Mbabane contains one European ward and two native wards. Sixty-eight patients were admitted during the year, and 1095 out-patients were treated. Further accommodation has become necessary, and it is hoped to enlarge considerably the scope of the institution as finances permit.

THE PELLAGRA PROBLEM AND AN AMERICAN JURY.

WHILE the scientific world has been wrestling for a hundred years or more with the perplexing problem of what causes pellagra, and without being able to come to a definite decision as to which of the conflicting theories is the correct one, an American jury has given its verdict without waste of time in favour of the "toxic-zeistic" etiology of the disease. The trial of an action is mentioned in the *American Journal of Tropical Diseases and Preventive Medicine*, the editor of which, however, seems to have his doubts about the case, since he expresses the opinion that "it reads like a hoax." The plaintiff brought an action for damages against a railway company for giving his daughter pellagra under the following circumstances. A horse straying on the line was run over and killed by a passing train, the body being subsequently buried in a field in stiff clay at a depth of 6 ft. and at a distance of 281 ft. from the plaintiff's well. Evidence was brought to show that shortly before the accident the horse had had a feed of maize, and that the corn had "spoiled" in the dead animal's stomach, the poisonous material from which had gradually soaked into the surrounding soil and ultimately found its way into the plaintiff's well, thereby giving pellagra to his daughter who drank the water. The jury came to the conclusion that the "spoiled" corn had been the cause of the pellagra, and awarded damages to the plaintiff to the amount of 1000 dollars. In commenting upon the case the editor of the journal from which we have obtained the above particulars expresses a doubt whether any supreme court would ever confirm such a decision, and in this view we entirely concur.

ASTROLOGY IN MEDICINE.

To the Editor of THE LANCET.

SIR,—Like yourself, I am unable to withstand the appeal that Mr. Pearce makes to me. He asks me whether I think that Roger Bacon and Albertus Magnus were incapable of distinguishing truth from error. I hasten to assure him that in my opinion these eminent men were as incapable of making a mistake as I am myself. The experience of mankind throughout the ages shows that clever men never make mistakes. No clever general has ever been defeated in battle; no clever judge was ever upset on appeal; no clever counsel ever lost a cause; no clever theologian ever held an erroneous opinion, or at any rate an opinion that was held to be erroneous by other clever theologians; no clever doctor ever made a wrong diagnosis; no clever schoolboy ever needs to have his exercises corrected; in fact, ability and infallibility mean the same thing.

Mr. Pearce is certainly right in pouring contempt upon my argument that Copernicus overthrew astrology; at least, he would have been right if I had made the statement, or if I had called it an argument.

I should be most happy to accept Mr. Pearce's challenge to debate this important subject before a learned society were it not that I am at present immersed in a much more important investigation, which absorbs my whole time and attention. That Saturn, Jupiter, and Mars, in conjunction in Aquarius, must have produced the Black Death in the following year is patent to everyone and needs no demonstration, but it required the insight of genius to discover that the burning of York Minster was due to the superabundance of snails in a certain back garden early in the same year. It is the peculiar merit of the adept, be he an astrologer or merely an haruspex, to recognise the significance of such coincidences. It seems to have escaped altogether the observation of the vulgar that this year of grace 1913 has been characterised no less by the superabundance of snails in back gardens than by the number of conflagrations initiated by suffragettes. The causal nexus needs no proof; but if it did, proof would be found in the fact that in Ireland, from which snails were banished by the beneficent action of St. Patrick, and where there are no back gardens, the backs of the houses being in front, there has been no suffragette incendiarism. I will not pursue the subject further in this place, but if Mr. Pearce wants any further information he will find it in my forthcoming book, "De Conflagrationibus et de Multitudinibus Helicidarum in Hortulis Posticis."—I am, Sir, yours faithfully,

Dec. 13th, 1913. CHAS. MERCIER.

A WEEK-END BREAKDOWN IN THE TELEPHONE SERVICE.

COMPLAINT was made recently in a letter to the *Times* by a correspondent whose wife was being treated in a nursing home in London, and who found at 6 P.M. on a Saturday that the telephone apparatus at the home was out of order. Owing to the incidence of Saturday evening and Sunday 40 hours elapsed before a mechanician with a couple of screws put the matter right in a few minutes, but meanwhile the husband had found, in spite of strenuous efforts, that it was impossible to get any repair effected earlier. As he observed in the letter referred to, quick communication not only with anxious relatives but with the physician or surgeon attending a patient may be necessary, and, of course, such a breakdown might occur in the medical attendant's house. When it is considered that the telephone is now a recognised necessity (as well as a luxury) of modern life, and that very few telegraph offices are open on Sundays, it will probably be agreed that the complaint made was a just one. No one wishes to interfere with the working man's Sunday upon frivolous pretext, but very many have to work on Sundays purely in order to cater for pleasure seekers, and the provision of a few men to keep the telephone service in working order stands upon a different footing.

THE BATHS OF MATLOCK BATH.

ON Dec. 12th a small party of London medical men travelled to Matlock Bath, Derbyshire, at the invitation of the proprietors of the Royal Hotel and Baths, and spent a pleasant week end in the beautiful Peak District. Opportunities were given for inspection and trial of the bathing establishment. This occupies the basement of the hotel, and receives its water-supply from the warm spring having its source in the grounds. The bath houses are very well equipped for the administration of the various baths, douches, packs, and other hydrotherapeutic measures commonly prescribed. In addition to these the management have secured from the hot springs of Battaglia, in Northern Italy, a continuous supply of the volcanic mineral deposit known as fango, which is employed with success on the Continent in the form of the fango pack. The special feature of this substance is its power of retaining heat, which makes it of value as an application in painful chronic diseases. The accommodation at Matlock Bath is so good that it deserves to be better known to the medical profession.

F. E. K.—In the case mentioned by our correspondent, nutriment would probably be in liquid or semi-liquid form.

H. M.—There is no violation of medical ethics in assuming the courtesy title, provided that no claim is made to the possession of a University degree.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

PLYMOUTH MEDICAL SOCIETY, Athenæum Chambers, Athenæum-lane, Plymouth.
SATURDAY.—8 P.M., Clinical Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.
MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced.
In 1913:—
Dec. 16th-20th (Aberdeen).—Red Cross and National Health Service Exhibition.
In 1914:—
April 14th-18th (New York).—Fourth Congress of the International Surgical Society.
,, 20th-23rd (Wiesbaden).—Thirty-first German Congress for Internal Medicine.
May 1st-Nov. 1st (Lyons).—International Town Life Exhibition.
July 6th-11th (Blackpool).—Twenty-ninth Congress of the Royal Sanitary Institute.
,, 8th-13th (Edinburgh).—Congress of the Royal Institute of Public Health.
Aug. 3rd-8th (London).—Sixth International Dental Congress.
,, 10th-15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.
Sept. 7th-12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Purvis Oration

ON

SOME POINTS IN THE DIAGNOSIS AND TREATMENT OF GRANULAR KIDNEY.

Delivered before the West Kent Medico-Chirurgical Society

By SAMUEL WEST, M.D. Oxon., F.R.C.P. Lond.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—The list of distinguished men who have preceded me as Purvis Orators shows what a great compliment it is to be invited to deliver this oration. I appreciate the honour very highly, and I trust that the contribution of to-night will not fall short of the standard set by my predecessors.

Dr. Purvis, in whose honour this oration was established, was a practitioner of wide experience, to whom the clinical side of medicine would most forcibly appeal, and in casting about for a subject I tried to select one which I thought would have met with his approval. Granular kidney seemed to me such a subject. It is a common disease, the interest of which is ever new, for it is constantly appearing in unexpected shapes, prepares for us many surprises, is by no means rarely overlooked, and presents many points of theoretical interest and of practical importance which may be worthy of our consideration. Although in the later stages the disease is past cure, still by an early diagnosis I believe much may be done to minimise its gravity, diminish its risks, and delay its progress.

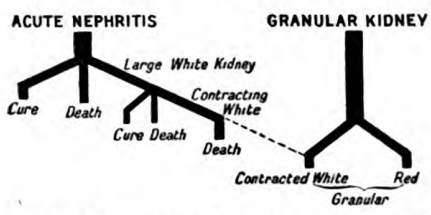
ETIOLOGY.

Granular kidney is an entity. It is a true disease, for it has definite morbid lesions, and definite clinical signs associated with them, which render diagnosis easy during life.

Shrunken kidneys were long known and described, but it was not until Gull and Sutton wrote that this affection was recognised as a disease. They drew attention to the changes in the blood-vessels and heart which were associated with the renal lesions, and gave the disease the name of "arterio-capillary fibrosis." Since then discussion has never ceased to rage as to the relation between the vascular and renal changes. The possible relation is threefold: (1) the renal changes may be primary, and lead to the vascular; (2) the vascular may be primary, and the renal secondary; or (3) both the renal and vascular changes may be joint results of some common cause. In spite of more than 40 years' discussion the problem is still unsettled.

Granular kidney is the best name for the disease, for it is the one generally accepted and best understood. Granular kidneys would be more accurate, for both kidneys are always affected and to a similar degree. The lesions are symmetrical and bilateral, never unilateral or local. This symmetry may be used as an argument in favour of some general cause to which the vascular and renal lesions alike are due, and there is the analogy of peripheral neuritis to support it. For peripheral neuritis, if bilateral, is always due to some general cause of a toxic character, like poisoning by alcohol or arsenic; whereas if it be unilateral, it is the result of some local cause. All local affections of the kidney, whether leading to shrinking or not, may be at once cut off, for there is not such a thing as granular kidney in which one kidney alone is affected.

Granular kidney is a form of chronic interstitial nephritis, yet all forms of chronic interstitial nephritis, even if bilateral, are not granular kidney. For instance, the gouty kidney, so-called, is a mixture of interstitial fibrosis with cell degeneration, yet gout has nothing essentially to do with granular kidney, for even in long-standing gout the kidneys need not be granular, nor is gout more than an accidental—i.e., not a necessary—accompaniment of granular kidney.



Clinical Evidence and Morbid Anatomy.

Both gout and lead are frequently given as causes of granular kidney. They are not infrequently associated with it, yet the true relation is probably the contrary to that suggested, the patients being especially liable to these affections, because their kidneys are granular and elimination defective, so that they are not causes of granular kidney, but its consequences.

Granular kidneys are usually small, but not necessarily, for they may be large and considerably above normal weight. Just as in alcoholic hepatic cirrhosis the liver may be large or small—i.e., above or below normal weight—so may granular kidneys. Renal cirrhosis would not be a bad name if it were understood that the whole of the renal organ—i.e., both kidneys—must be involved, as is the whole liver.

Two forms of granular kidney are described, the *contracted white* and the *contracted red*, and it is suggested that the difference in colour connotes a difference in cause, the white being the result of past inflammation and the red not. If this were so it ought to be capable of easy proof. Acute nephritis may certainly as a pathological process lead to interstitial change and some fibrosis, and in the end it may be to extreme wasting and contraction—i.e., to granular kidney; but if this often happened there ought to be no lack of clinical proof of it, for acute nephritis is a common affection enough, and its symptoms are too obvious to be overlooked. Yet clinical evidence is strikingly defective; I have looked for it for years, and have not seen a single clinical case which I could regard as conclusive, though I have met with many that pointed to an opposite conclusion. The two forms of granular kidney, the contracted white and the contracted red, are about equally common in the post-mortem room. If the contracted white kidney be as common as this, and the theory stated be true, the history of antecedent acute nephritis ought to be frequently obtained, and yet it is not.

It is impossible during life, either from the clinical history or symptoms, to forecast with probability whether the kidney will be white or red. There is, of course, the same chance of

guessing rightly as there is in tossing a halfpenny, but no more. I do not believe, therefore, that there is any difference between the contracted white and the contracted red granular kidney

except the accidental one of colour. The suggestions of morbid anatomy must be in harmony with clinical experience. The clinical evidence in this question is utterly against the theory. The conclusion is unavoidable that the theory is wrong. The diagram shows the difference in theory and the dotted line where the clinical evidence is lacking.

If there is little evidence to prove that acute nephritis leads to granular kidney there is plenty to prove the converse. It is common enough for an adult to come under observation with the first attack of acute nephritis in which the condition of the heart and vessels and even advanced changes in the retina show conclusively that the kidneys are granular and of date long antecedent to the onset of the acute nephritis. The correct conclusion seems to be that acute nephritis in the adult frequently occurs because the kidneys are already unsound.

SYMPTOMS.

Granular kidney is often overlooked because there are for a long time no symptoms at all, or if there are any they are misleading and point to almost any part of the body rather than to the kidneys. Yet so soon as granular kidney is thought of the diagnosis becomes clear, and all difficulty in interpreting the symptoms vanishes. It is generally the pulse that gives the clue, for so soon as the finger is placed upon the radial the characteristic thickening of the artery and the increased tension raise at once the question of granular kidney, and further examination soon makes the diagnosis certain. As compared with the thickening of the arterial wall and the increased tension in it the character of the pulse wave is unimportant.

The characteristic symptoms of granular kidney are: (1) the arterial thickening; (2) the increased arterial tension; (3) the characters of the urine; (4) the hypertrophy of the heart; and (5) the retinal changes. Upon each of these I have a few remarks to make.

Arterial Thickening.

Arterial sclerosis is a term which leads to much confusion, for as a general term it is a mere translation, and indicates nothing as to the nature of the thickening or its causes. But as a special term it is often used to denote that form of arterial thickening met with in granular kidney. The use of the same term in both a general and a special sense tends to confusion, and it would be well if the term could be eliminated from our terminology altogether.

Dr. F. W. Andrewes[1] has recently published an important report upon the forms of arterial change as met with in the post-mortem room. The monograph is of special importance as showing how common such changes are, and how widespread and advanced they may be without giving any definite symptoms by which they can be recognised during life. Many of these lesions are not associated with appreciable thickening of the walls, and do not, therefore, concern us in our present consideration.

Those that are associated with thickening fall into two well-marked clinical groups.

1. The first is commonly called *atheromatous*. This is a patchy, nodular, irregular degeneration, widespread but not universal, affecting especially the aorta itself, the cerebral vessels, and some of the middle-sized vessels, such as the radial and temporal. This is the usual degeneration of advancing life, and has been called senile. Dr Andrewes would subdivide this group into two forms, the senile and the nodular. The *senile*, in which the changes in the media are prominent, and some degree of calcification is the rule. The *nodular*, which commences in the intima, but involves the media later, and ends in the characteristic lesions of atheroma; this may occur in earlier life. The two changes are generally combined as age advances, and so for clinical purposes may be considered together.

2. The second group is that following abnormally high blood pressures, and is especially common in chronic renal disease. It affects the media especially, which is at first hypertrophied and then becomes fibrotic, but it is associated later with changes also in the intima. A good descriptive name is wanted for this, but it is often called arterio-sclerosis.

3. The third group is syphilitic, a local gummatous change involving primarily the intima, often multiple, but not generalised, affecting the aorta and cerebral vessels especially. This does not affect the radial or temporal artery, and therefore raises no difficulty in connexion with granular kidney.

If, then, the artery at the wrist is thickened there are two chief changes to consider, the atheromatous and the renal. These may be distinguished by age. Thus in the early half of life atheroma is unlikely; while in the latter half, though atheroma is common, the renal form cannot be excluded, for granular kidney may occur at any age, even in the very young and in the aged.

In the young adult there is one form which is not often referred to, yet it is of importance. I hardly ever lecture on arterial thickening without soon seeing some fine, healthy, athletic young student who has felt his arteries, found them abnormally palpable, and has jumped to the conclusion that he must have renal disease. In such a case the arterial thickening is not an arterial degeneration and a sign of disease, but a physiological hypertrophy and evidence of extremely vigorous life. Violent muscular effort leads to hypertophy of the muscular coat of the arteries as it does of the heart. It is most marked in the most athletic and healthy, such as gymnasts or great oarsmen, and we may assume that they would not be capable of such sustained physical effort if this hypertrophy did not occur. I am glad to draw attention to this form of thickening, as it is not so generally recognised as it ought to be. On the other hand, it must be borne in mind that a similar degree of thickening in one who is not a great athlete would be pathological. This physiological hypertrophy disappears in the artery, as it does in the heart, when the call for it is over, and leaves no trace behind. I do not know of any instance to show that arterial degeneration can be fairly referred to it.

Are the arteries invariably thickened in granular kidney, and must they necessarily be? Perhaps not. I have seen a few cases, at any rate, in which the other signs made the diagnosis certain, and yet there was no thickening of the radial sufficiently obvious to attract attention, for the thickening was not more than was compatible with the normal for that age.

The thickening in the early stage of granular kidney is largely muscular, as can be shown by the effect of nitrite of amyl, which relaxes the muscular tissue, but has no action on fibrous tissue. The thickening felt in the radial can be seen with the

[1] Report of the Medical Officer, Local Government Board, 1911-12.

ophthalmoscope in the retina, where the arteries show that wide and brilliant streak to which the graphic name "silver-wire arteries" has been given. Silver-wire arteries do not occur with any other form of arterial thickening except that associated with granular kidney, and are therefore pathognomonic.

Arterial Tension.

Arterial tension is the next subject for consideration. What we require to know is the tension or pressure in the arteries *between* the pulse beats. It is this pressure which converts the intermittent flow of blood into a constant stream, and upon which the nutrition of the tissues in large measure depends. We hear a great deal nowadays of blood pressures, but these are systolic pressures and measures of the force of the heart beat and pulse wave. The tension is not the systolic but the diastolic pressure. The systolic and diastolic pressures are often confused together, yet they ought to be kept quite distinct from one another.

The character of the pulse wave depends upon the force of the contraction of the left ventricle and the amount of blood driven into the arteries, modified by the resistance of the arterial wall and of the capillary area.

The same systolic blood pressure might give very different pulse curves. The crest would be high and the wave short if the resistance were low, and the crest low and the wave long if the resistance were high, thus producing the low, flat, long wave of the sphygmographic tracing of the so-called renal pulse.

An illustration will make my meaning clear.

A youth of 21 was suffering from advanced aortic incompetence. The systolic blood pressure was 180 mm. or more, yet the pulse was one of low tension owing to the defective nutrition and consequent loss of tone and the immediate collapse of the artery so soon as the wave had passed, owing to the regurgitation. Although the systolic blood pressure was high the diastolic tension was very low, and the patient was suffering more from low diastolic pressure than from the high systolic pressure, and to have reduced the systolic pressure by treatment would obviously have done harm.

There are many instruments which measure the systolic pressure, but none I know of which satisfactorily determines the diastolic pressure. In my opinion no instrument is yet invented which will take the place of the educated finger of the thoughtful physician.

The arterial tension in granular kidney varies. It ought to be above normal. It were better that the patient had not got granular kidney, but having granular kidney he ought to have a raised tension. With a low tension the patient is not so well, and will not be better till the pressure rises again. There is a sort of average raised tension for granular kidney, which cannot, however, be well expressed in figures. The tension may rise above this or fall below it, and may then require appropriate treatment, but to attempt to reduce the average raised tension of granular kidney to the normal for health is a mistake and will do harm.

What is curious and not generally known is that the tension is subject to *fluctuations* of a peculiar kind, so that when the finger is on the pulse the tension is felt to rise and fall at short and irregular intervals. This is quite plain to the finger, but I have never yet succeeded, in spite of many attempts, in demonstrating it by sphygmographic tracings. I have only observed these fluctuations in the later stages of granular kidney when the patient was very ill, but they are by no means rare then.

Hyperpiesis.

Though high tension is a cardinal symptom of granular kidney, it is met with not infrequently without arterial thickening or any other evidence of granular kidney. This has been called *hyperpiesis*, and it deserves a special name, for it is a distinct clinical condition. It is met with in persons of great energy, who work and live at high tension and are not happy unless they do. They do two men's work and often two men's play as well. They live freely, yet without what can be called exactly excess. In fact, they enjoy life to the full.

The condition seems to be confined to the male sex. At any rate, I have not seen any case in a woman, even in those who lead strenuous lives. The blood pressure ranges round about 200 mm. Their life is one of high pressure; indeed, they probably could not live the life they do without a high blood pressure. High blood pressure for such persons is their normal condition, and it cannot be reduced with impunity. The most drastic measures may be employed till the health becomes seriously affected, but the blood pressure remains as high as ever. All that the treatment has done is to nake the patients unhappy and incapable of their work. The drastic treatment is given up; they return to their ordinary mode of living, begin again to enjoy life, and soon are as hard at work as ever.

It can hardly be doubted that in the end such abnormal pressure will tell upon the vessels, and lead in time to some of those degenerative changes which Dr. Andrewes has described. Cardiac hypertrophy or failure may occur, or some vascular trouble develop, especially in the brain. These risks may be provided against in general ways, but not directly through the blood-pressure. The high blood pressure in their case is their normal condition, without which they would not be what they are—in popular parlance, they are built that way. Given the choice, they would rather have their high blood pressure with its risks and enjoy their life, than have their pressure lowered and lose their enjoyment of life.

The following is a typical case of this class.

A man, aged 48, about 5 ft. 10 in. in height, and weighing 13½ st., came to see me. He said he had been working very hard, felt tired, and wanted a holiday. He had taken a good one and felt now perfectly fit, but before going back he wanted to be overhauled to satisfy himself that he was all right. He was a man of fine physique and looked perfectly well. I could find nothing wrong with him except a slight increase of pulse tension. This was obvious enough. I wish I had measured it, but I did not think it necessary. He returned to work, lived his usual strenuous life, and remained perfectly well for two or three years.

Soon after that I saw him again, and I was shocked at his appearance. He was thin and anæmic, and looked like a man with malignant disease. He told me that he had lived his ordinary strenuous life till one morning six months previously. He had gone to bed well, but on rising he felt faint and giddy. The medical man, finding his blood pressure 180–200 mm., said he had had a narrow shave of apoplexy, bled him freely once or twice from the arm, and kept him in bed for some weeks upon very low diet. After a time he got up, feeling very weak and miserable For some time longer he continued with a greatly restricted diet and led an invalid life. Then finding he got worse instead of better he came to see me again.

I examined him carefully and failed to find any organic disease. The only thing abnormal beyond his appearance was the high blood pressure of 180 mm. He told me that it had been at that height all the time, and that dieting and treatment had had no effect upon it whatever. I considered him to be suffering from starvation; I ordered him a good dinner with some champagne. He had it and felt all the better. I advised him to continue with a liberal but plain diet. He soon picked up and looked a different being. In two or three weeks' time he was well enough to go home. I cautioned him to live at a lower rate. I heard subsequently

that he had gradually resumed his ordinary way of living, though he was careful in respect of wine and tobacco, delegated as much of his work as he could, and took more frequent holidays.

Though the medical man had no doubt good reasons for his anxiety at the commencement of the patient's illness, it is clear that the lowering treatment had been continued too long until the health suffered seriously. It is interesting to know that in spite of the stringent and lowering *régime*, and the effect this had had upon the health, the effect upon the blood pressure was *nil*.

I saw the patient again two years or so later. He had been in perfect health, and was passing through London on his way home after a good holiday abroad. The weather was very hot, and he was overcome one day with what he called a faint. When I saw him there was slight weakness of the left arm which he complained of, as well as some thickness of speech, and the left side of the face was somewhat smoothed out, and moved imperfectly. He had evidently had some incomplete thrombosis of one of the subdivisions of the right Sylvian artery. In a few days he had greatly improved and was able to continue his journey to his home, which he reached safely. My account of him at present is incomplete, but I hear he is much better, though not quite well or strong enough to undertake his old work. This attack is, no doubt, the consequence of the degeneration in his arteries to which I have said the high pressure was likely to lead. The most careful examination failed throughout to give any evidence of renal disease. The arteries were not at all thickened—indeed, if anything, they were unusually thin and supple for his age.

Albuminuria.

Of albuminuria there is not much that I need say. The amount of albumin is usually small, sometimes merely a trace. The most important fact about it is that it may be absent at some time of the day or even be absent altogether for days or weeks. As a rule, however, it is persistent, and does not vary much in amount from day to day or at different times of the day.

Albuminuria is a symptom, and not a disease. It is of importance because it ought not to be, and is a sign of something wrong. Its significance varies especially with age. In schoolboys and young adults it is common, and is then often called physiological, but physiological it cannot be, though it need not be renal. In schoolboys it is met with in two types: (1) in one the schoolboys are well developed, muscular and active, and apparently in vigorous health; and (2) in the other the boys are rather weedy, pale, or overgrown. In either case it is an affection of the age period and disappears as the boys grow up.

There is another class of the kind which has been called accidental albuminuria, and which is of importance. This is met with in athletes, university crews in training, football players, young recruits after drill—in fact, in young adults who are using their muscles violently. It disappears when the muscular effort is given up, and is not followed by any permanent mischief.

As long as albuminuria occurs as the only symptom in the young it is probably of no significance, but if it be associated with other signs, and especially with arterial thickening, even in slight degrees, more caution must be taken in pronouncing it to be of no gravity. For it may be the early state of granular kidney, for this is a disease which commences in early life and is not really rare in the quite young. Even when albuminuria is the single sign, its gravity increases with every year of age after 25, because of the increasing probability of its being due to granular kidney.

Even when a history of acute nephritis is obtained in earlier life, so that the albuminuria is in all probability due to some renal change it does not follow that the kidneys are involved to any great extent. For the acute nephritis may have resolved completely in one kidney and not in the other, or in both kidneys to a great extent—it may be of 9/10, 19/20, or 49/50. Yet the little patch of chronic mischief left will be quite sufficient to account for the amount of albumin present. In such cases the condition of the kidney must not be assumed on theoretical grounds, but must be determined by careful investigation. If there is no evidence of renal inadequacy the albuminuria may be of little importance, and life run its ordinary course to its usual span.

As the amount of albumin lost is so small, it is too little in itself to have any effect upon the health, and if the health suffer it is the result of other causes. The albuminuria need not, therefore, be drastically treated. Moreover, the strictest dieting often produces no effect upon it, though it may have a disastrous effect upon the health. Even if the albuminuria could be made to disappear, its disappearance would not show that the disease was cured, but a useful clinical indication would have been lost. As a matter of fact, treatment in these cases has little effect or none at all. As with raised arterial tension, so with albuminuria, treat it if need be, but beware of over-treatment.

Albuminuric Retinitis.

Of albuminuric or renal retinitis there are two forms—the one pathognomonic of granular kidney, the other not.

The one is *inflammatory*, and might continue to be called retinitis. It is associated with much swelling of the disc and retina, and might therefore be called *exsudative*. It is exactly the same as other forms of exsudative or inflammatory retinitis, and cannot be distinguished from them, and so it comes that mistakes in diagnosis have been made, for example, between granular kidney and cerebral tumour, especially when headache has been the prominent symptom.

The other form is *degenerative* and not inflammatory. It would be better to describe it as *renal retinal degeneration*. This is *sui generis*, and pathognomonic of granular kidney. I do not know of any retinal change like it, and when it is present granular kidney may be diagnosed with certainty.

The *acute exsudative form* is probably toxic in origin. It is met with in acute nephritis as well as in chronic. In acute nephritis it may resolve and completely disappear, leaving no defects of vision behind. In chronic nephritis it is more serious, and does not as a rule resolve because the renal condition has got beyond the stage of recovery.

There is no relation between the two forms, and it is not true to speak of the exsudative form as a later stage of the degenerative. They are distinct conditions, associated sometimes together, and due to different pathological conditions.

The *degenerative form* being pathognomonic of granular kidney deserves a little further consideration. It consists in the presence of small white glistening patches like crystals of cholesterin or the scales of a fish. These patches may be very tiny and require very careful searching for, but when found they are conclusive. They are patches of retinal degeneration and atrophy. In the most marked form they constitute the cart-wheel or spoke-like radiations round the yellow spot, but, of course, this is only an advanced condition. The spots are more interesting and important when they are few and tiny, for they may be accompanied by no defects of vision and be discovered only by

routine ophthalmoscopic examination. They may be associated with hæmorrhages, but these present nothing characteristic.

The spots being patches of degeneration rarely, if ever, disappear. I used to say never, and practically this is really true; but if the renal condition improve they possibly may, and I think I have had one or two such cases under my own observation. What is very important is that they may be present and characteristic when the other signs of granular kidney may be open to question, so that they are of the greatest diagnostic importance.

Renal retinal degeneration is a late symptom or a sign of advanced disease. It used to be said that it meant that the patient had not more than two years to live. That is in a general way true when the degeneration is well marked, but it is not possible to say how long it had existed before it was looked for. I have seen the tiny spots long before any grave general symptoms appeared, and I have met with cases of advanced degeneration with much hæmorrhage which lasted to my knowledge five years and seven years respectively.

A year or two ago a gentleman, 40 years of age, was sent to me with the history that he was attacked with uræmic fits about six months previously, and on examination of the eye advanced albuminuric degeneration with much hæmorrhage was discovered. A grave prognosis was given, with which I entirely agreed. I certainly thought the case almost hopeless, but I put him upon renal extract, which was steadily persevered with for many months. He gradually recovered and is now well. The fact of his complete recovery from the eye as well as the renal symptoms makes me feel some hesitation about the correctness of the diagnosis, but the condition seemed plain enough at the time, and no one who saw him when first ill, either physician or ophthalmologist, had any doubt. I have never seen any other case like it, and I record it for what it is worth.

TREATMENT.

I cannot at the end of such a paper as this go into the details of ordinary treatment, nor is it necessary when addressing an audience of practitioners. I will merely refer to a few points upon which an expression of opinion may be useful.

Of the causes of granular kidney we really know nothing. Many conditions to which it has been attributed—e.g., gout, lead, syphilis, and alcohol—though they may be contributory or aggravating, are certainly not prime causes. The disease is of such long duration and its commencement may be traced so far back in life that its beginnings elude our study. It is a very common disease now, but whether this means that it is increasing in frequency or only that it is more often diagnosed cannot be determined. One is tempted to believe that it is really on the increase, and to connect it with the strain and stress of modern life, for it is often met with in persons with a perfectly clean bill of health who have simply lived strenuous and anxious lives.

Granular kidney *in the early stage*, though capable of certain diagnosis, leads to no symptoms. The general health seems so good as to justify the patients in disbelieving the diagnosis and disregarding to their own detriment the advice based on it. At this stage treatment is precautionary and directed to obviate the risks to which the disease leads, of which the chief are cardiac failure, rupture of vessels, and nephritis; therefore, physical strain, exposure, and habits of excess, especially in diet and drink, should be avoided. The life led should be of studied moderation in all things, of such a sort as would tend to keep the physical health at the highest level.

The risk at this stage is that the albuminuria which has been discovered should lead to its drastic treatment. The amount of albumin lost daily is too small to have of itself any effect upon the general health. Treatment has little or no effect in materially reducing its amount, still less in causing its disappearance, and drastic treatment by diet will injure the general health. Treat if need be, bnt do not over-treat.

There is another risk by no means negligible—viz., that of alarming the patient so much as to convert him into a renal hypochondriac whereby there is added to the renal disease, which is bad enough in itself, a neurotic condition of no slight gravity. To dwell too much upon the gravity of the case in the early stages to the patient is therefore undesirable, and, considering the long lease of life these early cases have, not warranted by facts.

When symptoms arise they must be treated on general principles, bearing in mind especially the nature of the disease which underlies them. Thus if cardiac symptoms develop over-stimulation must be avoided because of the increased blood pressure this would cause. For this reason digitalis is of doubtful value, and caffeine is a better remedy.

Vascular tension ought to be somewhat raised in granular kidney, and cannot be reduced much without detriment unless it be excessive. On the other hand, if the tension be low it must be raised, for with a low tension the patient is not so well, and will not be better until the tension has risen again. It is the tension that determines the use of digitalis. If the tension be raised it will do harm, but if low, and especially if associated with cardiac failure, digitalis is the best drug for the purpose. So soon, however, as the desired effect has been produced it should be suspended.

Hæmorrhage may not be serious except when it affects the brain. Fortunately, cerebral hæmorrhage rarely develops without some warning, and if the warning be taken may be avoided. These warnings are often given by hæmorrhages elsewhere—e.g., into the conjunctiva or retina.

Epistaxis is common and may actually be useful, in so far as it may stave off a hæmorrhage into the brain. Epistaxis may be the first thing to bring the patient to the medical man. It may produce extreme exhaustion from which the health may never recover, so that the disease appears as if it dated from the epistaxis.

Hæmaturia is not uncommon and may lead to errors of diagnosis and treatment. Thus stone in the bladder may be wrongly diagnosed and operated for, or, if the hæmaturia be associated with cachexia, may raise the suspicion of malignant disease. As a rule, the hæmaturia is small in amount and does not require active treatment.

Generalised rushes are not uncommon in the later stages. They are generally more or less acute, toxic in origin, and of very grave prognosis. Acute general eruptions of any kind, if associated with albuminuria, are always serious, and if occurring in the course of granular kidney generally mark the beginning of the end.

For *sleeplessness* and *nervous restlessness* at night no sedative is better than cannabis indica, which in my experience is the great hypnotic in granular kidney. Opium and its preparations may be given if required without the risks once attributed to them.

Uræmia is often ushered in by headache, great restlessness, foul tongue with gastric and intestinal disturbances. I do not propose to enter into the

question of the treatment of uræmia, except to say that it may often be staved off by active treatment if its imminence be recognised in time. For this purpose free purgation, active diaphoresis, and oxygen inhalation are of great use.

Of drugs there is none so good as pilocarpine, which in my experience is the great standby in granular kidney. It has been asserted that it is a risky drug to employ. That is not my experience. I have used it largely for years with great benefit, and I have never seen any untoward effect produced by it.

Chronic Uræmia.

The symptoms which develop in the later stages of granular kidney are of a very miscellaneous character. They are accompanied by great impairment of the general health, and the asthenia and cachexia which result are often the most prominent features. This condition is often called chronic uræmia, but it is so different from acute uræmia that it is confusing to use the same name for both. *Chronic renal toxæmia* would be a better term.

Similar symptoms arise in chronic parenchymatous nephritis. They may rapidly develop in cases of suppression of urine; experimentally in animals where both ureters have been tied or both kidneys removed, or in man where both ureters have been accidentally ligatured, or one kidney has been removed, the other being absent or grossly diseased, as well as in some extreme cases of acute nephritis. A profound and rapidly progressive asthenia thus develops, generally without any fits or ordinary signs of acute uræmia; and of this the patient dies in about ten days or so without other obvious reasons except the asthenia.

Usually this condition is referred to poisoning by some substance which the kidneys ought normally to get rid of, but cannot. What the substance, or substances, may be no one knows, except that it certainly is not urea, as the name implies. There is, however, another alternative—viz., that the nutrition of the body suffers so profoundly for the want of some substance normally prepared by the kidney for use in the body—in other words, for the want of some internal secretion.

Renal Extract.

Has the kidney such an internal secretion? So far the pathologists have not been able to prove this experimentally. With their failure we must fall back on clinical evidence, in the hope that this may show that chronic renal disease is favourably influenced by renal extract, just as myxœdema was proved to be by thyroid extract.

There is a difficulty unfortunately in preparing a reliable renal extract. I have tried various methods, and for a time used a glycerine extract. Messrs. Burroughs and Wellcome also attacked the problem, but without success, for they could get no preparation which was stable and could be preserved. I have consequently fallen back on an extract of kidney freshly prepared as required, using by preference the kidney of the pig as being a mixed feeder, rather than the kidney of a vegetable feeder like the sheep.

The great difficulty in obtaining evidence in favour of the usefulness of kidney extract in chronic renal disease lies in the fact that its use must be continued for weeks or months before results can be expected; generally patience is exhausted before the time required, and the treatment given up because signs of improvement are not immediate. Of course, in granular kidney the cases come under observation so late in the disease, when the mischief is so far advanced, that much benefit can hardly be looked for. Yet I have seen some of the symptoms, especially headaches, relieved by this means when they had resisted other treatment.

The most remarkable case I have met with is that which I referred to in passing when dealing with albuminuric retinitis. So extraordinary was this case that I must confess to the suspicion that the diagnosis of granular kidney must have been wrong. Still I felt quite certain of the diagnosis, as did the other medical men, when the case came first under observation.

Another remarkable case was as follows:—

The patient was a man, aged about 35, who had been attacked with acute nephritis some weeks previously. He had passed into the typical stage of chronic parenchymatous nephritis. He was passing a very large amount of albumin in the urine, was extremely anasarcous, with much ascites and a considerable pleuritic effusion on the right side. Both the abdomen and pleura had to be tapped more than once, but the fluid reaccumulated quickly. The man was sent into the hospital as a hopeless case. All the ordinary treatment was tried without success, the patient steadily went downhill, and the prospect seemed desperate. Renal extract was now given night and morning. In a few days the patient volunteered the statement that "Dr. Reynolds' extract," as he called it, was doing him good, and that he felt ever so much better. The improvement soon became obvious, the effusions and the dropsy disappeared, slowly at first and then rapidly, and in about three weeks had vanished. The albumin in the urine also rapidly decreased, and on leaving the hospital about six weeks later amounted to a mere trace. The man was carefully watched for some months. He went back to work and remained well.

I know there are rare instances in which rapid improvement in chronic parenchymatous nephritis occurs in what appear to be desperate cases. But I have never seen anything of this kind before, and I cannot avoid referring the result to the renal extract. In this view I was supported by those who had been watching the case with me.

My experience of some years now justifies me, I consider, in continuing and advocating the use of renal extract, but to be effectual in granular kidney it must be patiently and continuously persevered with for a long time.

CANCER RESEARCH.—The late Mr. Arnold Friedlander has left a sum of £5000 to be applied as his executors may direct towards increasing the knowledge of the cause, characteristics, and effects of cancer and allied diseases and the best means for prevention, alleviation, and cure.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, Jan. 13th, 1914, at 4 P.M., when the Rev. S. Scobell Lessey, M.D., chaplain-superintendent of Abbotswood House, Temple Memorial Home for Male Inebriates, will open a discussion on the Male Inebriate.

LIVINGSTONE COLLEGE.—The annual report and statement of accounts for the year 1912–13 show an improvement in the financial position of this college. The adverse balance of £701 which existed at the beginning of the year has now been reduced to £621, and it is hoped that the college will soon become practically self-supporting. Reference is made to the Livingstone Centenary Fund of £10,000, which will form the nucleus of an endowment fund Towards this object £660 has already been subscribed. Dr. C. F. Harford, the principal of the college, who was mainly responsible for its foundation, will, it is announced, retire in the summer of 1914. The college does good work in providing sufficient medical training to missionaries who may be stationed in places where it is impossible to obtain the services of a fully qualified medical man, and it is deserving of support.

CONCUSSION CATARACT: ITS MEDICO-LEGAL ASPECT; WITH NOTES OF AN UNUSUAL CASE.

BY PERCY DUNN, F.R.C.S. ENG.,
SENIOR OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL; LATE LECTURER ON OPHTHALMOLOGY AT THE WEST LONDON POST-GRADUATE COLLEGE.

CONCUSSION of the eyeball as a cause of cataract is well recognised. Hence "concussion" cataract is a term applied to opacity of the lens which has followed contusion of the eyeball in which no penetration of the contusing body or rupture of the ocular coats has occurred. The contusion may be caused either directly or indirectly. Directly, when the eyeball has been suddenly compressed anteriorly by some force by which an increase in its transverse diameter has followed. Indirectly, when the body generally has been subjected to a sudden jar, in the effects of which the eyeball partakes. Nearly 50 years ago—in 1866—Dyer pointed out that cataract ensued as the result of judicial hanging. Similarly blows upon the head, jumping or falling from a height and alighting upon the feet have also been cited as among the causes of concussion cataract. Whatever may be the nature of the contusion to which the eye is subjected, the resulting opacity of the lens is due to a rupture of the capsule. Most commonly this takes place equatorially, but both anteriorly and posteriorly the same may occur. It may be stated that some hold to the opinion that a rupture of the capsule is not necessary to the development of cataract in these cases—that a cataract can, and at times does, follow concussion of the eyeball without any lesion of the capsule. The evidence, however, in support of this view is not satisfactory or conclusive. It depends mostly upon personal impressions. No post-mortem opportunities have ever arisen to determine the point. Cases which have been quoted in proof of the non-rupture capsular theory have been those in which the lental changes have been delayed for some time after the eye has been injured. But reasonably enough it may be assumed that in these cases an incomplete rupture was present at first which afterwards became complete. Moreover, to determine an equatorial rupture by examination is not possible Norris sums up the matter by saying: "Quite a large number of cases of cataract are on record where, after blows on the eye or in its vicinity, the lens becomes opaque without any visible rupture of the capsule, but so long as no such case has come to autopsy, and we are familiar with ruptures of the posterior capsule, they are always open to the suspicion that there has been a rupture at some point not accessible to examination."

A fact which seems to bear upon the incidence of these cases of concussion cataract is the inconsistency in the nature of the force causing the lesion. A severe blow upon the eye may be followed by rupture of the choroid without the lens or its capsule being injured. A blow may even cause rupture of the eyeball, but again the lens may escape injury. And yet, as will be gathered from the notes recorded below, a most trivial injury to the eye was followed by cataract, to which the term "concussion" was applicable. The explanation of this inconsistency and of its effects, so far as the lens is concerned, may lie in the hypothesis that the lens capsule is not structurally perfect: that rupture of the capsule ensues as the result of concussion because of this structural defect. It is certain that concussion cataract would be of very frequent occurrence in ophthalmic surgery were the capsule to rupture upon all occasions upon which the eye was subjected, directly or indirectly, to contusion. Fortunately, however, it is only rarely that such an untoward result occurs.

Subjoined are the notes of a case which has recently been under my care.

A man came to the West London Hospital on Nov. 18th, 1912. He gave the history of an accident to his right eye, which occurred on August 24th previously. While engaged in his occupation—that of working a milling machine—a chip of steel, described as of about the size of 1/16th of an inch, suddenly became detached and struck his right eye. The foreman of the shop having examined the eye, stated that there was no trace of the piece of metal, but only an abrasion of the cornea. The pain having subsided, the man was able to resume his work after an interval of half an hour. On the following day, owing to discomfort in the eye, he attended the Royal Free Hospital. He was told by the house surgeon that two small foreign bodies were present on the cornea. These were removed, and he was informed that the eye would be well again in a few days. The sight was then quite unaffected. About seven days later he first noticed slight blurring of the vision in the right eye. This blurring continued and increased, and it was on account of this that he sought advice.

On examination the right eye was quiet; there was a small, superficial, irregularly shaped opacity upon the inner quadrant of the cornea, below the pupillary area. The iris was intact and its movements free and natural. The lens was cataractous. Projection good; fingers at 4 inches. Tension normal. There was no evidence of penetration by a foreign body; nevertheless, a skiagram was taken, which proved negative. The man continued his occupation until the end of January of the present year, the condition of the injured eye not causing him any inconvenience. About this time proceedings were begun for the recovery of compensation, and on legal advice, in consequence, he ceased his occupation. On August 28th I extracted the lens; subsequently with + 2 cyl. axis 85° N.E. ē + 10 sph. the vision was 6/6 and with + 2 cyl. axis 85° N.E. + 14 sph. J. 1 at 7 inches.

On Nov. 10th, after several postponements, the case was heard in the High Court before Mr. Justice Channell, and after two days' trial with a special jury the plaintiff was awarded £273 and costs. The machine which had been provided him to work with was proved to have been defective, hence the cataract was held to have been caused through the culpable negligence of his employers. In giving evidence, it was essential to point out that although the plaintiff had recovered the vision in the injured eye, binocular vision had been abolished and that the sight so regained would only be of limited use as long as the other eye remained sound. Presumably in awarding the damages the jury were influenced more by the fact that the injury had necessitated an operation than by the result of the latter.

One or two further points remain for comment. The accident which occurred is one of the commonest in ophthalmic surgery. Workmen in metal employment are exposed to it almost daily, so much so that fragments of metal impacted upon the surface of the cornea are often removed by a particular workman, by whom has been acquired in the shop some skill in doing so, with the aid usually of the dirty blade of a pocket knife. In other cases the injured workman places himself before a

powerful magnet when this is available. And yet in the above case, despite the trivial degree of concussion which a fragment of steel, stated to be only 1/16th of an inch in size, could have caused, a traumatic cataract followed. The damages awarded seem to be rather excessive; the amount almost equals that which insurance companies offer for permanent and total loss of vision in an eye. Stress also was laid by the plaintiff's counsel, as well as by the judge in his summing up, upon the fact that the medical evidence was unchallenged. But the solicitors for the defendants, after hearing from me in regard to the case before the trial, were satisfied that further medical evidence was unnecessary.

Wimpole-street, W.

THE RELATION OF THE THYROID TO ANTITOXIN.

BY RUPERT FARRANT, F.R.C.S. ENG.,
SURGICAL REGISTRAR TO WESTMINSTER HOSPITAL.

IN a preliminary paper[1] thyroid hyperplasia was described as occurring in many diseases, and it was shown, among other conditions, that it was produced by the action of diphtheria toxin in horses and guinea-pigs. It was suggested that the hyperplasia was associated with increased secretion which could be traced into the blood, for it was found in four estimations that diphtheria antitoxin contained more iodine than normal serum, and that when fed to a normal rabbit it caused death in a manner similar to thyroid feeding, while it had no such effect on a thyroidectomised rabbit. Normal horse serum produced no ill-effect when fed to a rabbit. The thyroids from four horses were found to be in a condition of hyperplasia following repeated injections of diphtheria toxin, the extent of the hyperplasia being in inverse proportion to the antitoxic value of the serum. It was suggested that thyroid hyperplasia with the increased secretion in the blood was associated with the formation of antitoxin, and that the thyroid had an antitoxic function. This appeared to be borne out by experiments on guinea-pigs, as 10 out of 13 pairs survived longer if thyroid feeding was combined with the administration of diphtheria toxin, and 4 out of 5 survived when given the serum of a thyroid-fed rabbit with the toxin. I have continued to work on this subject, and while I am able to confirm my results in many points, some of the deductions require modification.

The production of thyroid hyperplasia in disease will be more fully described in my next paper; it was found to occur in a number of diseases (toxæmias) in man, and was produced in some 50 guinea-pigs by the injection of diphtheria toxin, and was also obtained by the injection of abrin and ricin. So it can definitely be said that thyroid hyperplasia is caused by some toxæmias.

The Detection of Thyroid Secretion in the Blood.

1. *The estimation of iodine.*—It was thought that the production of thyroid hyperplasia would lead to the presence of an increased secretion in the blood, and that this would be detected by an estimation of the iodine contained in the serum. Any increase in the amount of iodine in an antitoxic serum would suggest that the toxin used for its preparation had produced a thyroid hyperplasia. The different brands of the various sera were obtained, and the iodine estimated with the following results:—

Normal horse serum.—Contained faint traces.

Dysentery (two brands).—(1) Contained 1·83 parts of iodine per 1,000,000 of serum; (2) contained 2·04 parts.

Antimeningococcic serum (4 brands).—(1) *Nil*; (2) *Nil*; (3) contained 1·41 parts of iodine per 1,000,000 of serum; (4) contained 1·66 parts.

Antiplague serum (4 brands).—(1) *Nil*; (2) 1·82 parts of odine per 1,000,000 of serum; (3) 1·98 parts; (4) 2·04 parts.

Antiscorpion serum (1 brand).—Contained *Nil*.

Antitetanic serum (4 brands).—All four contained *Nil*.

These estimations were made before it was realised that the horses had been rendered immune to more than one toxin. The third and fourth samples of antimeningococcic serum were obtained from horses that had previously been used for the preparation of diphtheria antitoxin, so the amount of iodine in the serum cannot be ascribed to the sole action of meningococcic toxin on the thyroid, especially as practically no thyroid change is found in meningococcic meningitis in man. The estimation of the iodine is open to another fallacy—the apparatus used for drawing off the horse's blood may perhaps have been contaminated with iodine from the use of potassium mercuric iodide as an antiseptic; this applies equally to the normal horse serum. These fallacies are sufficient to render the estimations valueless.

2. *The effect of feeding rabbits on commercial diphtheria antitoxin.*—Three rabbits were fed on commercial diphtheria antitoxin (see table); they were given 2000 units a day mixed with their food. The serum was obtained from several different horses, which precluded the estimation of the total amount of iodine given to any one rabbit. Three samples contained 2·25, 2·3, and 3·1 parts of iodine per 1,000,000 of serum. The rabbits developed the same symptoms as those produced by thyroid feeding—loss of weight, tachycardia, and fur changes; and the post-mortem changes were similar to those found in rabbits dead from thyroid feeding—i.e., absence of fat, muscular wasting &c.

Amount of antitoxin.	Feeding days.	Original weight.	Final.	Per cent. lost.
(*a*) 46,000 units	23	840 g.	535	40·0
(*b*) 63,000 ,,	33	1,880 g.	1,260	33·0
(*c*) 66,000 ,,	34	1,510 g.	1,120	25·8

These experiments agree with those of the original paper, and the conclusion drawn is that diphtheria antitoxin (commercial) contains an iodine-containing substance with a similar action to thyroid secretion.

The Estimation of Iodine in Diphtheria Antitoxin.

A series of iodine estimations were made on samples of diphtheria antitoxin which had been collected free from any possible source of extraneous iodine.

Horse.	Antitoxic value.	Iodine content.
Baby	2 units	*Nil.*
Sarah	200 ,,	Very faint traces.
Lincoln	300 ,,	2·7 parts per 1,000,000.
Fleck	300 ,,	*Nil.*
Liverpool	500 ,,	Faint traces.
Durham	500 ,,	Very faint traces.
Matilda	600 ,,	Faint traces.
Alfred	600 ,,	,,
—	700 ,,	Very faint traces.

Three others contained *nil*.

Further estimations were made on unlabelled duplicated samples to determine the value of the faint traces with the following results:—

Normal serum.—(1) *Nil*; (2) faint traces.
70 units.—(1) *Nil*; (2) faint traces.
300 units.—*Nil.*
350 units.—*Nil.*
400 units.—1·81 parts per 1,000,000 of serum.

These estimations were made by Oswald's modification of Baumann's method; the smallest amount

[1] Transactions of the Royal Society of Medicine, November, 1912.

that can be estimated by this means is 1·6 parts per 1,000,000. The estimations were made for me by Mr. S. Bosworth at the Westminster Hospital Medical School laboratories, and I am very grateful to him for the exceptional care and patience which he took over them.

The conclusion drawn from these estimations is that the quantity of iodine contained in these sera is so small that it is on the border line of the minimal discernible amount, so that in two estimations on a serum one may show evidence of faint traces whilst in the other it may pass undetected. There is thus no evidence of any increased amount of iodine in the sera of high antitoxic value.

Observations on Antitoxin.

The thyroids were obtained from 15 horses that had received increasing doses of diphtheria toxin for a period of a year to 18 months. It was found that they presented a varying degree of hyperplasia, but that when they were arranged in order, from the highest degree of hyperplasia to the lowest, they were in the reverse order of the antitoxic value of the serum. The apparently normal thyroid corresponded to the serum with the highest antitoxic value. The following table shows the final dose of diphtheria toxin which was given to 10 horses and the previous and final antitoxic value of the serum. The table is arranged in the order of the degree of thyroid change from an extreme hyperplasia to an apparently normal gland.

Order of thyroid hyperplasia.	Previous antitoxic value.	Dose of toxin.	Final value antitoxin.
		c.c.	
1. Sarah	200	500	200 units.
2. Baby	—	½	2 ,,
3. Lincoln	350	800	300 ,,
4. Fleck	300	800	300 ,,
5. Martha	300	1900	300 ,,
6. Marjory	400	1800	400 ,,
7. Liverpool	600	1800	500 ,,
8. Durham	400	700	500 ,,
9. Alfred	500	1800	500 ,,
10. Matilda	500	1450	600 ,,

With the exception of No. 2 the series graduated from a condition in which the cells were increased in number, the vesicles small in size though full of colloid, down to large vesicles packed with colloid and lined by a single row of flattened cells. The thyroids were taken 7–10 days after the last injection; the degree of hyperplasia varied slightly with the date. The extent of the thyroid change was not dependent on the dose of toxin given, for while the change produced in No. 2 from the injection of one-half c.c. was extreme, 1800 c.c. in No. 9 produced no change. The hyperplasia appears to vary inversely with the antitoxic value of the serum, and a rough estimate of the antitoxic value can be deduced from the appearance of the thyroid. (Baby was bled out as it went off its legs, and was unable to withstand even small doses of toxin; the thyroid was in a condition of hyperplasia with colloid absorption.)

Has the Administration of Iodine any Antitoxic Action to Diphtheria Toxin?

1. *Thyroid feeding.*—Fifty-eight guinea-pigs were arranged in 29 pairs, each of a pair being similar in appearance and weight. They were injected with different doses of diphtheria toxins. Half were otherwise untreated; the other half were given doses of thyroid powder. Eighteen—that is, nine pairs—were injected with doses of diphtheria toxin from 1 c.c.–0·1 c.c. daily (a single minimal lethal was 1 c.c.); half of these pigs were otherwise untreated, the other half at the same time and 24 hours previously were given thyroid powder by the mouth in doses from 0·06–0·01 gramme daily until they died. Four of the guinea-pigs given thyroid outlived the controls, two died before, and three died on the same day.

2. *Thyroid injection.*—(*a*) *Fresh thyroid.*—Six guinea-pigs were divided into three pairs, and every one received a single dose of toxin, from 1·4–1·0 c.c. Three were otherwise untreated; the other three were given a corresponding dose of an emulsion made by pounding up 6 fresh guinea-pigs' thyroids with saline. Two of the guinea-pigs given thyroid lived the same number of days as the controls; the other one died two days before.

(*b*) *Colloid solution.*—Six guinea-pigs were divided into three pairs; they were given 0·6, 0·5, 0·4 c.c. of diphtheria toxin daily. Three were otherwise untreated, the other three were given daily injections of a liquid proprietary preparation of thyroid; the doses corresponded to the doses of toxin. Two of the guinea-pigs given thyroid lived as long as the controls; the other one died four days before.

The results indicate that thyroid treatment has no antagonistic action to toxin.

Is the Serum of a Thyroid-fed Animal Antitoxic?

Two rabbits were fed with 0·5–0·3 g. of thyroid powder by the mouth every day for seven days; one had lost 42 per cent. of its weight, the other 15 per cent. They were bled out and the blood defibrinated and centrifugalised. The serum was injected in doses from 1 c.c.–0·25 c.c. into 14 out of 28 guinea-pigs arranged in pairs. They were all given a single dose of 1½ times the minimal lethal dose of diphtheria toxin. Three of the guinea-pigs given the serum survived, 2 lived longer than the controls, 6 died on the same day, and the other 3 died before the controls. From this it is deduced that the serum of a thyroid-fed animal has practically no antitoxic value.

If these results be taken together with those described in my preliminary paper, it may be said that 47 out of 94 guinea-pigs were given some variety of thyroid preparation to protect them from diphtheria toxin. Of the 47, 7 survived, 16 lived longer, 17 died on the same day, and 7 died before the controls. From this it is deduced that the antitoxic value of the thyroid is negligible.

The thyroids of those guinea-pigs that had been treated with some form of thyroid preparation together with diphtheria toxin were found to show less colloid absorption than those receiving toxin without thyroid. In a preliminary paper this was put forward in support of the antitoxic action of the thyroid. But further investigation shows that this appearance is due merely to the combination of the hyperplasia produced by the toxin with the increased colloid arising from thyroid treatment. It was found that the thyroids taken from cats, rabbits, and guinea-pigs which had been thyroid-fed showed an increased amount of the colloid material with a greater staining capacity. This would give an appearance of a lessened hyperplasia in those animals that had been given thyroid as well as diphtheria toxin.

Summary.

Certain diseases, and especially certain toxæmias cause hyperplasia of the thyroid gland in man and animals. Among these diphtheria toxin has been examined especially, and it is found that a small dose is sufficient to elicit hyperplasia in a susceptible animal, but that as immunity is acquired

the thyroid no longer undergoes hyperplasia under the toxin. The hyperplasia thus decreases as the antitoxic value of the serum increases. The thyroid gland, in other words, is protected from the action of the toxin by the presence of antitoxin in the serum. There is no reason to suppose that any special relation exists between antitoxin formation and the thyroid gland—for example, the latter is not antitoxic itself.

In some cases commercial antidiphtheritic serum fed to rabbits caused death with the same symptoms as thyroid feeding; this may be due to the serum of partially immunised horses containing an unusual amount of thyroid secretion from the hyperplasia. But this could not be controlled, as the amount of iodine in pure serum was too small for accurate estimation. The pure antitoxic serum does not appear to contain any estimable increase of iodine.

The experimental work, except the iodine estimations, was done at University College, in Professor A. R. Cushny's laboratory, and I am very much indebted to him for his care and advice. I am also indebted to Dr. H. H. Dale and Dr. A. T. MacConkey for the material which has enabled me to carry out the work.

MEDICAL SECTION.

Yellow Fever.—Tuberculous Rheumatism.

A MEETING of this section was held on Dec. 16th, Dr. A. E. GARROD, Vice-President, being in the chair.

Dr. J. W. SCOTT MACFIE and Dr. J. E. L. JOHNSTON communicated a paper on some Experiments and Observations on Yellow Fever. They said that in 1909 Seidelin described bodies in the blood of yellow fever patients which he believed to be the parasite of the disease, and he had since published a series of papers on the same subject. As far as they were aware his observations had as yet only been confirmed by Hernandez (1912). The authors had undertaken experiments and observations at Yaba, near Lagos, during the course of an epidemic of yellow fever at Lagos, which commenced in May, 1913. It was not long before they discovered in the red corpuscles bodies which they believed to be identical with the paraplasma flavigenum of Seidelin. They had found these elements in practically every case of yellow fever which they had examined, and also in guinea-pigs, dogs, and rats which had been inoculated from human cases. Guinea-pigs had proved to be the most susceptible of the animals with which they had experimented, and they had succeeded in conveying the paraplasma bodies by subinoculation. These bodies were by no means always scanty, but were, as a rule, sufficiently numerous to be a valuable aid in diagnosis, and, further, an assistance in the study of yellow fever. Thus they had found them in the blood some days after the subsidence of the fever, when the patient was apparently convalescent, and they had succeeded in infecting guinea-pigs by inoculations made as late as the eighth day. In natives yellow fever was often a mild, almost trivial, illness, and patients often insisted that they felt well after but one or two days in hospital. In their own homes they would, no doubt, go about freely at this stage of the disease, while the paraplasma bodies were still to be found in the blood. If, as they believed, these bodies were the parasites of yellow fever, these patients should be capable of infecting mosquitoes and of further spreading the disease. In other words, they would be infectious far longer than the generally ascribed period of three days. The successful inoculation of dogs and rats suggested possible subsidiary means by which the disease might be kept endemic, in spite of stringent sanitary regulations. Moreover, the inoculation of laboratory animals opened the way to an exact study of the etiology of yellow fever, of the parasite of the disease and its cycle in its vertebrate and invertebrate hosts, and of the therapeutic effects of various drugs. Seidelin had examined a number of their blood films, and had confirmed their view that the bodies were identical with the paraplasma flavigenum.

Dr. NATHAN RAW read a short paper on a case of Tuberculous Arthritis.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Dec. 12th, Mr CHARTERS J. SYMONDS, the President, being in the chair.

Dr. F. PARKES WEBER showed a case of Chronic Myelocytic Leukæmia treated by benzol, &c. The patient, aged 59, was admitted to hospital in August, 1913. The spleen was hard and greatly enlarged. The liver was also enlarged. The superficial lymphatic glands appeared unaffected, excepting for slight swelling of those in the groins. The blood picture was typical of myelocytic leukæmia. The teeth and gums were unhealthy. The stomach contents after a test breakfast contained no free hydrochloric acid. The patient did not seem acutely ill, though he was weak. Brachial systolic blood pressure, 110 mm. Hg. Dr. R. Gruber reported that the fundi were normal. Wassermann and Pirquet reactions were both negative. There was often slight evening pyrexia until Sept. 29th, but since then there had been none. As he had already been treated by Roentgen rays elsewhere it was decided to make a trial of benzol-therapy, introduced by A. von Korányi and G. Kiralyfi, of Budapest, in 1912. Gelatine capsules, each containing a mixture of 0·5 grm. benzol and 0·5 grm. pure olive oil, were given thrice daily from August 15th to 23rd; from August 23rd to Sept. 2nd the same dose five times daily; from Sept. 2nd to 16th, 1 grm. thrice daily; and from Sept. 16th to Oct. 20th, 1 grm. four times daily. The benzol treatment was then discontinued as it had led neither to decided objective nor to subjective improvement, and Roentgen ray treatment under Dr. James Metcalfe was immediately commenced. Since then the spleen had obviously diminished greatly in bulk and the quality of the blood had improved. On August 14th (before the benzol therapy) the blood examination gave: Red cells, 3,400,000 per c.mm.; white cells, 130,000 (polymorphonuclear neutrophiles 45·2 per cent., and myelocytes and myeloblasts 29·9 per cent.). On Oct. 20th (when the benzol-therapy was discontinued) the blood examination gave: Red cells, 2,532,000; white cells, 219,000 (polymorphonuclear neutrophiles 57·14 per cent., and myelocytes and myeloblasts 25 per cent.). On Dec. 2nd the blood examination gave: Red cells, 5,350,000; white cells, 76,200 (polymorphonuclear neutrophiles 55 per cent., and myelocytes and myeloblasts 31 per cent.). In addition to the above treatment the patient on August 25th, was given intramuscularly 20 c.c. of fresh defibrinated blood from a healthy man, but this had no obvious therapeutic effect.

Mr. ARTHUR EVANS showed a case of Suppression of Urine in a boy, aged 11, after operation for acute appendicitis, cured by double nephrotomy. The boy was admitted into hospital on a morning in August, 1913, and was operated upon the same night for acute appendicitis. The tip of the appendix was acutely inflamed and contained pus, which, as the appendix was being delivered through the wound, burst through the appendix wall and was caught upon a gauze pad without fouling the peritoneal cavity. There was a little free fluid in the peritoneal cavity. A rubber drainage-tube was inserted through the wound to the site of the appendix; the rest of the wound was sewn up. Saline solution was administered per rectum. Next day the boy was sick twice. During the 24 hours 8 pints of saline were given. On the third day 10 pints of saline were given per rectum. No fresh abdominal signs manifested themselves. The drainage-tube was replaced by a gauze plug. After 2 grains of calomel in $\frac{1}{3}$-grain doses the bowels were moved twice. On the fourth day the patient was quite comfortable and his bowels were moved twice; the temperature reached 100° F. at mid-day, pulse 86, and respiration 34. On the fifth day at 2 A.M. he complained of pain in the left loin, and vomited thrice. He was given 3 minims

of oil of cajuput and 1 minim of tincture of iodine at 4 A.M. The pain became easier later in the morning. The boy was sick after each feed of lemonade and milk with barley water. At 11 A.M. he passed about 3 drachms of urine deeply stained with blood (the deposit after centrifugalising showed blood and bacteria, both bacilli and streptococci; no casts). On the sixth day the patient still had some pain, which was now in both loins. His colour was not good and the pulse was weak. No urine had been passed since 11 A.M. on the previous day, but now about 3 drachms were voided, looking like undiluted blood. This contained blood, pus, black pigment granules, oxalates, and a few large cocci, but no casts. Hot fomentations to the loins had been continued since the day before. At 5 P.M. a hot pack was given, as vomiting was persistent. The boy seemed more comfortable until 7.30 P.M., when he had a convulsion; 2 pints of citric acid solution were given per rectum. At 8 P.M. he was unconscious and the pulse feeble; 3 pints of saline were given intravenously, and 2 pints per rectum. A hot-air bath was given. The skin did not become moist. At 8.45 P.M. the pulse was only just perceptible. At 9.20 P.M. the patient was taken to the operating theatre and Mr. Evans rapidly exposed both kidneys and freely laid them open, cutting through the kidney substance and exploring the pelvis; no stone could be felt in either. Each kidney seemed much larger than normal, particularly the left, and each felt tenser than normal. From the left kidney a small piece was excised for microscopical purposes. Both kidneys bled profusely, and both were plugged with gauze packing. There seemed to be no urine in either pelvis. The patient was taken back to the ward and 10 minims of brandy were given hypodermically and 2 pints of saline subcutaneously. The next day at 12.15 A.M. the voluminous dressings had become sodden with urine as well as blood. So profusely did fluid discharge from the kidney incisions that fresh packings were frequently necessary. The bladder was washed out at 11 A.M. The pulse was much stronger and the patient was quite comfortable; he did not vomit and there was no further convulsion. He made an uninterrupted recovery. Dr. R. G. Hebb, who examined the portion of kidney removed, reported that it was in a condition of cloudy swelling. The urine had become normal.

Mr. T. H. KELLOCK showed four cases of Malignant Disease after treatment with radium. 1. A man, aged 66, who was admitted to hospital in July, 1913. Six weeks previously he had first noticed on the upper lip an ulcer which had gradually increased in size but had not caused him much pain. On admission the greater part of the upper lip was the seat of a hard-edged, rather deep ulcer, extending almost from one angle of the mouth to the other, and into the mucous membrane nearly to the junction of the lip and alveolar margin of the jaw. Its hard, everted edge was clearly seen on the outside of the lip. There were no palpably enlarged lymphatic glands. The tongue showed a mild chronic superficial glossitis. Five days later a tube containing 82 mgr. of radium was inserted into the lip from the end of the growth, the inside of the lip and gum being protected by a thin lead plate 2 mm. thick, fixed to the teeth. The radium tube was left in for 24 hours. Marked inflammatory reaction followed, and a typical radium necrosis occurred on the lower lip; all the hair on the upper lip fell out. Nothing further was done for two months, when it was found that almost the whole of the growth had disappeared, leaving, however, a hard ulcer on the inner aspect of the lip towards the left side, and some induration around it. The ulcer was about a quarter of an inch in diameter and very superficial. A tube containing 82 mgr. of radium was again inserted into this part and left in for 18 hours. Inflammatory reaction was again marked, and a superficial ulcer appeared on the outer side of the upper lip. This took about a fortnight to heal, and at the end of that time the ulcer on the inside of the lip had disappeared. The condition showed still a little hardening towards the left side and a certain amount of scarring of the whole lip, but there was no ulceration, and the movements of the lip seemed very little impaired. Microscopical examination: Squamous-celled carcinoma. 2. A man, aged 35, who had first noticed that his throat was sore and that he had a swelling in the neck in January, 1913. In June, 1913, he attended hospital, where a piece of growth was removed from the back of the tongue for examination. In the same month he was an in-patient at another hospital, where the growth was considered to be malignant and inoperable. He was admitted under Mr. Kellock's care in July, 1913, with a growth about the size of a walnut towards the left side of the back of the tongue, deeply ulcerated on the surface with hard edges. The mass was in contact with the soft palate, and appeared to infiltrate the glosso-epiglottic fold on the left side. The movements of the tongue were impaired with difficulty in swallowing. The left cervical lymphatic glands were markedly enlarged, very hard, and only slightly movable; one enlarged gland could be felt on the right side of the neck opposite the angle of the lower jaw. A week later, under an anæsthetic, 82 mgr. of radium were inserted into the base of the growth and left for 15 hours. Inflammatory reaction followed, the soft palate and base of tongue being covered with a yellowish membrane. After a week a marked diminution in the size of the growth was noticed, and this continued until it had practically disappeared in 14 days, and at the same time the glands in the neck became markedly smaller and more movable. The reaction in the mouth had disappeared in 21 days. On readmission at the end of September there was practically no sign of the growth in the tongue, but the cervical glands were still considerably enlarged. These were removed by operation, the whole of the chain on the left side and one gland on the right side being excised. The wounds healed by first intention and the patient was discharged. When shown there was nothing to be seen or felt of the growth on the tongue, and the neck on the left side seemed clear; there was, however, a little hardness about the scar on the right side of the neck. 3. A woman, aged 50. The patient stated that she had had a thin yellow discharge from the right ear for two years, but had had no pain until August, 1913, when a tumour began to grow at the meatus; then the discharge became less, but was stained with blood. She had only been deaf since the appearance of the growth. For about a fortnight she had noticed that the right side of the face was weak. On admission a hard growth about the size of a filbert was growing from the margin of the right meatus, involving the pinna and the skin in front of the ear. The surface was slightly ulcerated, with a foul-smelling discharge. There was no marked enlargement of the cervical lymphatic glands. The facial nerve on the right side was completely paralysed. Three tubes of radium, containing altogether 144 mgr., were inserted into the growth, and left in for 24 hours. The inflammatory reaction was not very marked. About a month later, on readmission, most of the mass had disappeared, and in its place a small slough was visible at the upper part of the meatus, surrounded by an ulcerated surface discharging slightly. Radium was again inserted in two tubes containing altogether 104 mgr. for 24 hours. Inflammatory reaction was absent up to the time of her leaving hospital, and she had not been seen since. Microscopical examination: Squamous-celled carcinoma. 4. A man, aged 55, a clay pipe smoker. About a year ago he first noticed that he had a sore on the lower lip, but did not consult a doctor about it until November, 1913. On admission to hospital there was a typical malignant ulcer of the lower lip, a little towards the right side, the ulcer measuring $1\frac{1}{8}$ in. in length by $\frac{5}{8}$ in. in breadth, with very hard edges and slight discharge from the surface; the surrounding parts were not much affected, but were covered with a thick brown crust. No enlargement of lymphatic glands was observed. Under local anæsthesia a tube containing 82 mgr. of radium was inserted into the lip under the growth, the upper lip being protected by a thin sheet of lead. The tube was left in position for 21 hours. Inflammatory reaction followed almost immediately, and 15 days later the greater part of the growth had disappeared, though the lip still showed signs of this inflammatory reaction, being swollen and slightly ulcerated, so that there was little difference to be observed between the original situation of the growth and the rest of the lip. On the inside of the lip there was a marked condition of radium necrosis, the surface being covered by the usual yellowish membrane.

Dr. F. S. PALMER showed a case of Congenital Heart Disease and Hemiplegia. The patient, a woman, aged 22, had always been blue as long as she could remember, and suffered from shortness of breath on the least exertion; but she went to school in the usual way. She had had scarlet fever at the age of 6, and attacks of acute rheumatism at 17 and again

at 19½ years of age. In March, 1912, she had an attack of hemiplegia of sudden onset on the left side, involving the facial muscles. She was aphasic for a fortnight and then recovered her speech. Before the hemiplegia she was left-handed, but she now used both hands equally well. After admission to hospital alarming syncopal attacks and cardiac dyspnœa kept her in the recumbent position for nearly two months. Under treatment she had steadily improved in health, but she still walked with a slight limp, and there was some weakness of grasp in the left side. The points of interest appeared to be:—1. The degree of cyanosis, probably from birth, with remarkable clubbing of the fingers and toes, and polycythæmia. 2. The cardiac impulse could be felt best during active respiration about the sixth intercostal space in the anterior axillary line. Percussion and skiagrams showed no enlargement of the heart to the right, but the organ was generally increased in size and apparently lay with its long axis on the diaphragm. A loud, harsh murmur could be heard with its maximum intensity at about the junction of the third left costal cartilage with the sternum, and occupied the whole period between the first and second sounds, ending sharply with the latter. The murmur was well heard over the sternum in that position, but it was not audible over the whole of the cardiac area, nor was it conducted up into the back. Nothing could be heard at the back, and there was no evidence of any pulmonary complication. The absence of any other physical signs in the heart and large thoracic arteries pointed to some kind of congenital malformation with possibly superadded rheumatic endocarditis, or endopericarditis, as an explanation of the apparent hypertrophy of the left ventricle. 3. The hemiplegic symptoms had to a great extent disappeared. The patient used her left hand and wrote unusually well with it. Her deep reflexes were equal but slightly increased, and the plantar response was flexor on both sides.

Mr. W. G. SPENCER showed a case of Latent Fracture of the Patella. The patient, a man aged 46, was exhibited six months after the union by wire of a transverse fracture of the left patella, along with the photographs taken after the fracture and after the union. He sustained a sub-aponeurotic fracture from slight violence, after which he was able to walk nine miles and again 15 miles, also to go up and down stairs frequently until a week after the fracture, when, in stepping down one step, the aponeurosis tore widely with separation of the fragments.

Dr. F. J. POYNTON showed a case of Cleido-cranio-dysostosis, with signs pointing to pressure on the brachial plexus by the rudimentary clavicles. The patient was a girl aged 19. Neither clavicle had been properly formed. The fontanelles were very late in closing (about the age of 17). For the last five weeks the patient had had shooting pains in the inner side of the arm and the front of the chest and the right side; these had been getting worse. The teeth of the upper jaw were very irregular and ill-formed. Both clavicles were imperfectly ossified, each being in two pieces. The right arm showed a diminution in pulse when the shoulder was depressed, and there were areas of hyperæsthesia on the inner side of the arm and the front of the chest. The main point was the question of the pain and the appropriate treatment. (The case was reported in THE LANCET of Dec. 7th, 1907, by Dr. E. I. Spriggs.)

Mr. T. B. LAYTON showed a case of Swelling of the Upper Jaw in a boy, aged 18, who had noticed the swelling on his face for two months. The teeth were all present with the exception of the third molars, and as none of these were milk teeth no unerupted teeth were likely to be present in the front of the jaw. Mr. J. S. Cocks had examined them with the hot and cold tests and found them to be alive, nor could he find any evidence of caries, but reported that there was an acute inflammation of the pulp of the left lateral incisor. On transillumination the right side was opaque, the left was markedly translucent. On the left side there was a swelling of the maxilla, which bulged on to the face, the anterior two-thirds of the palate, and the inferior meatus of the nose. Externally it was oval and passed up to the lower mesial quadrant of the orbital margin, but above this the nasal process was felt to be of its normal shape. In the mouth the swelling did not cross the mid-line; the alveolar margin was expanded and not thickened; at the reflection of the mucous membrane from gum to cheek, in the space between the second premolar and first molar, was a circular area of a quarter of an inch in diameter where there was no osseous tissue in the wall of the lump. Above and behind this the zygomatic process of the maxilla could be felt. The crowns of the lateral incisor, the canine, and both premolars were rotated inwards.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held in the board room of the Great Northern Central Hospital on Dec. 11th, Dr. T. Wilson Parry, the President, being in the chair.—Dr. Constance Long, under the general title of "Psychotherapy," took the subject of Complex Formation in Relation to Hysteria and the Psychoneuroses. She gave a brief review of the history of hysteria throughout recent centuries, leading up to the latest theories on the subject. She said that Jung's word "complex" was useful; it embraced the "dissociated state" of the French school and "the foreign body in the unconscious" of Freud. A complex was made up of normal experiences and emotions, but in the case of a morbid development the emotional tone or "affect" has obtained an undue value because of its fixation to buried or forgotten experiences; it is thus thrown out of relation to the general stream of consciousness. This division of energy between the conscious and unconscious parts of the personality was the result of inhibitions and gaps in higher control, leading to a loss of will power, split-off states, &c. An example of dream analysis was given, and instances were offered of subconscious ways in which certain hysterical patients cherish their symptoms. This was not common to all hysterics, many of whom are most anxious to get well. It is the task of the analyst to disentangle the underlying nervous mechanism which conceals or distorts their unconscious wishes into symptoms. Dr. Long made a plea for a more rational understanding of the aims and methods of psychotherapy, since there are many cases in which it is the therapy of choice. It should not be left as a last resource, but be tried early in the treatment of a psychoneurotic.—Invitations had been issued to practitioners who had worked in the subject to take part in the after-discussion.—Dr. C. Lloyd Tuckey expressed his pleasure at having heard Dr. Long's excellent paper, and said that he was entirely in accord with the views she had brought forward. He described his own visits to the cliniques of Berkheim, Liébeault, Forel, and other continental authorities on that subject. He urged the importance of psycho-analysis in those cases where hypnotism failed, and quoted cases in proof of this. Finally, he advocated the great advantages of establishing psychotherapeutic clinics in our general hospitals for teaching purposes.—Dr. H. E. Wingfield thought that psycho-analysis should only be tried as a last expedient owing to the long time and considerable expense incurred. He described the conditions essential for successful hypnosis and his own method of induction. In his opinion the two chief essentials were concentration of attention and limitation of consciousness. His chief interest lay in the treatment of alcoholism, which he briefly described. The true dipsomaniac he regarded as hopeless, but the ordinary drunkard, if not cured, could be converted to a fairly good citizen, his attacks being greatly lessened by psychotherapeutic agency.—Dr. Helen Boyle (Brighton) said that she preferred to call her treatment "getting the run of people's minds" rather than psychotherapy. She expressed herself as entirely opposed to the sexual theory of hysteria and other neuroses. She quoted cases showing the value of treatment by suggestion in neuromimesis and early mental disorders and urged the importance of giving the medical student of the future adequate training in psychotherapy as part of his curriculum.—Mr. M. D. Eder said that in his experience psycho-analysis was not suitable for psychoses as dementia præcox, &c., but was eminently satisfactory in hysteria, neurasthenia, and the obsessions. Cases must, of course, be selected. It could not be regarded as an "all-round" treatment for every case that came to the consulting-room. Psycho-analysis required as much care, attention, study, and practice as a major surgical operation. Cases took a long time, at least three or four months, giving from five to six sittings a week. He supported Freud's view of the sexual origin of neuroses, pointing out the wide view that Freud took of sex, including therein affection, friendship, and parental and fraternal love.—Dr. Jessie Murray pointed out the importance of psychotherapeutic instruction in general

medical education.—Dr. Long replied that nothing gave a better insight into the workings of the human mind than psychotherapy. Many things and actions that before seemed unintelligible and incapable of explanation could be easily explained.

HARVEIAN SOCIETY.—A meeting of this society was held on Dec. 11th, at the Stafford Rooms, Tichborne-street, W., Dr. Leonard Guthrie being in the chair. —Sir Ronald Ross read a paper on the Study of Infections by Enumerative Methods, in which he drew attention to the advantages of modern investigation by groups of men working together under one head; indeed, he hinted that the time had now arrived when advance of tropical medicine could only be made by organised "team" effort. He described the investigations carried out by a small team working under his direction in Liverpool for two years on a sum of £900 granted to him from the Home Office. There was a vast amount to be done and several very useful advances and observations made. The team unfortunately scattered, and the work was abandoned when the money came to an end. The observations dealt chiefly with the intimate characters and phases of sleeping sickness, a new variety of which was actually discovered by the research, and also the result of drugs on this disease both in man and animals. Reference was also made to the real nature of blackwater fever and its experimental production on animals. The paper was clearly illustrated by lantern slides and micro-photographs, many of which were reproduced in natural colours.—Dr. Sidney P. Phillips thanked Sir Ronald Ross in the name of the society for the interesting lecture.

Reviews and Notices of Books.

John Hunter and Odontology.

By J. F. COLYER, L.R.C.P. Lond., M.R.C.S., L.D.S. Eng., Dental Surgeon to the Royal Dental Hospital of London and to the Charing Cross Hospital, &c. London: Claudius Ash, Sons, and Co., Limited. 1913. Pp. 214. Price 20*s.* net.

BY placing on record the substance of two recent museum demonstrations at the Royal College of Surgeons of England on Specimens of Teeth prepared by John Hunter, Mr. Colyer has produced a book which will be found of great interest to anatomists and teachers, whether acquainted or unacquainted with the original works of John Hunter.

The author opens with a brief sketch, compiled chiefly from the researches and writings of Drewry Ottley and Stephen Paget, of Hunter's life, and notes the tragedy connected with his manuscripts. He then proceeds to deal with "Teeth in General," "The Anatomy of the Human Teeth," "Hunter's Observations on Comparative Dental Anatomy," and "The Pathology of the Teeth of Animals." The larger portions of the first four chapters are composed of copious extracts from the Hunterian MS. Catalogue, while the remaining three contain full notes from the Anatomist's "A Practical Treatise on the Diseases of the Teeth, intended as a Supplement to the Natural History of these Parts." Mr. Colyer has made no attempt to write a fine book, but has bound together many quaint descriptions written by Hunter's master hand, and here quoted in the original language, by a commentary connecting the several subjects. Many of the illustrations are superb, though it is difficult to understand the reason why some should be slightly enlarged views of the objects described. The photographs of specimens exhibited in the collections of the Royal College of Surgeons of England and of the Hunterian Museum in the University of Glasgow will be a revelation to many readers. In the latter part of the book the illustrations permit comparison of the modern methods of pictorial reproduction with the century-old steel engravings which enrich the value of the original works, sometimes, we need hardly say, to the detriment of the former. Fig. 78 is repeated as Fig. 113, and we think the author would have been well advised to put full descriptive legends under the pictures.

The book will serve as a pleasant reminder of visits paid to the magnificent osteological and odontological collections in the Hunterian Museums of the Royal College of Surgeons of England and in the University of Glasgow, and emphasises the magnitude of the debt which the science of dental surgery owes to John Hunter.

A History of Chemistry from the Earliest Times till the Present Day.

By the late JAMES CAMPBELL BROWN, D.Sc. Lond., LL.D. Aberd. With a Portrait and 106 illustrations. London: J. and A. Churchill. 1913. Pp. 543. Price 10*s.* 6*d.* net.

Dr. Campbell Brown, who was professor of chemistry in the University of Liverpool, died in the spring of 1910. Previous to his death he had expressed the intention of revising his series of lectures on the history of chemistry and preparing them for publication. He looked forward to a time when he would be released from the duties of his chair, and thus find leisure for this work. Unhappily this release came only with death, but fortunately his valuable notes were gathered together by his cousin, Mr. Henry H. Brown, the editor of this volume, who may be congratulated upon the success with which he has dealt with the carefully collected materials. They provide very interesting reading and give a valuable insight into the historic developments of chemical science.

Broadly, the book is divided into two sections, the first dealing with ancient history from prehistoric times till 1500 A.D. and the second with modern history from 1500 A.D. till 1700 A.D. and onward. The first period covers the alchemical vogue and the second period the iatrochemical vogue. The modern history may be said to have begun when the baffled alchemists altered their point of view—when, in fact, they applied their minds to the search for knowledge instead of the search for gold. The iatrochemist, or chemist physician or apothecary, devoted his efforts to searching for the elixir vitæ, while the alchemist looked vainly for the philosopher's stone. Pharmaceutical chemistry was the creation of the iatrochemical period, although organic chemistry gained little ground, for the iatrochemists interested themselves in finding out the medical properties of the metals and their salts. Then came the phlogiston theory (1650 to 1775), around which a fierce warfare of words and views was waged. Foremost amongst the supporters of phlogiston were Cullen, Black, Cavendish, Priestley, Bergman, Scheele, and Kirwan, and yet these were the pioneers of the quantitative period. "The phlogistic theory failed through the absence of quantitative determinations by means of the balance, and so soon as the balance was applied to the investigation of chemical processes, the phlogiston hypothesis had to make way for another and more correct explanation." The quantitative period has reached a point of great activity at the present day.

The book contains some very interesting outlines, and chemical literature is certainly enriched by its

wealth of historical material. The late author must have laboured very hard to find this material, and his searchings have been so far rewarded as to have enabled him to preserve a continuity of treatment. No doubt the editor has done his share towards filling up gaps where the necessity arose, and genuine credit is due to him for his work of compilation.

Traité Clinique et Médico-légal des Troubles Psychiques et Névrosiques Post-traumatiques.

By R. BÉNON, Médecin de l'Hospice Général de Nantes. Paris: G. Steinheil. 1913. Pp. 456. Price 10 francs.

IN his introduction the author distinguishes between the study of psychiatry and the study of mental alienation. The former is constituted by the special clinical study of sensations, representations, ideas, emotions, passions, and morbid acts. Mental alienation is a social and medico-legal conception. In his book he proceeds to examine mental and emotional pathology from both standpoints, and he has collected from the literature an immense number of observations bearing on the development of pathological mental conditions after accidents. Regarded from the viewpoint of the documentary value of these cases, the merits of the work are considerable. Dr. Bénon's classification and annotations, moreover, add to the usefulness of the volume. He distinguishes (1) traumatic dysthenia, constituted by asthenia, prolonged or chronic, periodic dysthenia, asthenomania; (2) traumatic dysthymia, including anxiety neurosis, hypochondria, "sinistrosis," hysteria, and changes in character; (3) traumatic dysphrenia, viz., amnesia, Korsakoff's syndrome, confusion, agnosia, and dementia. In addition other symptoms and conditions, not readily classifiable, are included.

Some of the references to cases recorded in the literature are so brief that their value is somewhat discounted, but, speaking generally, Dr. Bénon has done a service to psychiatry in collating from so many and varied sources clinical data bearing on the problem of the relation of mental disturbance to preceding trauma.

An Introduction to the Study of Infection and Immunity, including Chapters on Serum Therapy, Vaccine Therapy, Chemotherapy, and Serum Diagnosis: for Students and Practitioners.

By CHARLES E. SIMON, B.A., M.D., Professor of Clinical Pathology and Experimental Medicine at the College of Physicians and Surgeons, &c., Baltimore. Second edition. London: Baillière, Tindall, and Cox. 1913. Pp. 325. Price 14*s.* net.

THE study of immunity has attracted so much attention and become so important in recent times that books dealing with this subject have naturally tended to multiply, and it is natural to open each new one with some suspicion that an unnecessary addition is being made to the existing stock. In the case of Professor Simon's book this fear is groundless, as we have presented to us an unusually good account of the very difficult matter with which it deals. The earlier discovered basal facts of immunity are, indeed, now so well established as to form an essential part of every student's mental equipment, but investigation progresses so rapidly that it is difficult even for those closely interested in pathology to keep themselves *au courant* with the latest discoveries and the hypotheses proposed to explain them, so that a book such as that before us is thrice welcome.

The first four chapters deal with the general nature of infection, with the offensive forces of pathogenic organisms, special attention being paid to the problem of aggressins and to the different kinds of poisons at work. The defensive action of the host is then considered, phagocytosis and opsonic power, bacteriolysis, and the army of antigens and antibodies being taken up in turn. Ehrlich's side-chain theory has a chapter to itself, which is followed by one on the various kinds of immunity, natural and acquired. Two chapters are devoted to anaphylaxis and its relation to disease, this difficult subject being lucidly treated. The practical application of active and passive immunisation to different diseases occupies the next two chapters, and the concluding two sections deal with chemotherapy as elucidated by Ehrlich's work and with diagnostic methods, such as the agglutination reaction, the Wassermann test, the tuberculin and luetin reactions, and so forth. The information given is full, clear, and as well up to date as is possible in a book dealing with so rapidly changing a theme. Illustrations are supplied where they are necessary, but are not "dragged in by the head and shoulder," as is not seldom the case in American books. There is also an adequate index. We congratulate the author on his work and commend it to the readers for whom it is intended.

Leitfaden zur Untersuchung der Zerebroflüssigkeit.

By F. PLAUT (Munich), O. REHM (Bremen), and H. SCHOTTMÜLLER (Hamburg). With 5 figures in the text and 21 coloured plates. Jena: Gustav Fischer. 1913. Pp. 150. Price 8.50 marks; bound 10 marks.

EXAMINATION of the cerebro-spinal fluid in nervous and mental cases is to-day a commonplace of clinical pathology; the information thereby to be gained is often indispensable. The usefulness of detailed knowledge of the state of the fluid in health and disease, moreover, seems to be augmented by each fresh discovery in the pathogenesis of nervous affections. A compendium such as the modest volume under review, is therefore very welcome. It is comprehensive, readable, accurate, well illustrated, and up to date.

An introduction on the anatomy and physiology of the cerebro-spinal fluid includes a description of the technique of lumbar puncture. The first part of the book contains an account of the chemistry, serology, cytology, and bacteriology of the fluid. The second part deals with the condition of the fluid in the diseases of internal medicine, in functional nervous and mental disease, peripheral nervous disease, the various forms of meningitis, organic diseases of the brain and cord, and every variety of syphilis.

We have formed a high opinion of the usefulness of this book. The information it contains is practical and set forth methodically to facilitate reference. There is a good index, and the illustrations serve all the purposes for which they are intended. They are clear, distinctive, and easily understood. We note, as a minor criticism, that there seems to be no reference to the condition of the fluid in intoxication by lead. The book can be heartily recommended to student and physician.

MISCELLANEOUS VOLUMES.

AT this season of the year a stream of reference handbooks, ever increasing in volume, makes its appearance, and we take an early opportunity of referring to several which have already reached us. They may be divided into three classes: (1) Books of general information on all sorts of subjects, topical and otherwise; (2) books restricting themselves to general information about a particular section of activity; and (3) directories and biographical lists of various classes of people.

Of the first class we have received three books, two of which are so widely and favourably known as hardly to need comment. *Whitaker's Almanack, 1914* (London: Whitaker. Pp. 904. Price 2*s.* 6*d.*), is a book whose utility has made it indispensable in the home and in the office. It should be mentioned that the Almanack has been increased in size by 32 pages, and some new matter has been added with regard to such things as housing and town planning, the increase in the cost of living, National Insurance, and other matters of topical interest.——*Hazell's Annual, 1914* (London: Hazell, Watson, and Viney. Pp. 592. Price 3*s.* 6*d.* net), edited by T. A. INGRAM, LL.D., is also a necessary companion to other books of reference, inasmuch as it contains a summary of current topics arranged in a convenient form, while a copious index considerably adds to the value of the book. A diary of the events of the past year is also an important feature of this publication.——*Who's Who Year Book, 1914–15* (London: Adam and Charles Black. 1914. Pp. 178. Price 1*s.* net), was called forth by the fact that for ready reference many books are spoilt by over-much reading matter, involving considerable search to pick out names and salient points from a mass of uneven print. The reduction of the information to the smallest required amount and its arrangement in an even tabular form throughout undoubtedly facilitate search. This plan is followed in the book named. Among the subjects so dealt with are the ambassadorial corps, the academies, the churches, clubs, House of Commons, Consular Service, directories and year books, Government officials, Royal Commissions now sitting, railways, race meetings, hospital staffs, the peerage, societies, schools, steamship lines, heads of universities, and other miscellaneous subjects, such as university degrees and academic costumes, authors' pseudonyms, pronunciation of proper names, winning owners of racehorses, peers' married daughters, and titled Americans. These are all arranged in lists, so that reference can be made with the utmost facility.

Of the second class three books call for notice. *The Official Year Book of the Scientific and Learned Societies of Great Britain and Ireland* (London: Charles Griffin and Company. 1913. Pp. 380. Price 7*s.* 6*d.*), to quote the title-page, gives "a record of the work done in science, literature, and art during the session 1912–13 by numerous societies and Government institutions." It is compiled from official sources, and contains in addition to the information already mentioned (in the shape of lists of the papers read in each society during 1912–13) the names of officials, conditions of membership, entrance fees, and so forth. The lists of papers read before the Royal Society of Medicine, Medical Society of London, British Medical Association, Lister Institute, United Services Medical Society, and the various hospital and provincial medical societies occupy pp. 313 to 371.——*The Englishwoman's Year Book and Directory, 1914* (London: Adam and Charles Black. Pp. 441. Price 2*s.* 6*d.* net), edited by G. E. HUTTON, is in its thirty-third year of issue. It answers the majority of questions that a woman is likely to ask with regard to education, the professions, social life, and philanthropic work, and affords evidence of growing activity in women's work. Among the interesting articles is one on Health Centres or School Clinics, by Miss Margaret Macmillan.—— *The Writers' and Artists' Year Book, 1914* (London: Adam and Charles Black. Pp. 156. Price 1*s.* net), also edited by G. E. HUTTON, is an invaluable source of information for writers and artists. It contains lists of the principal journals and magazines in English-speaking countries that accept and pay for outside contributions, of syndicates for MSS. and literary agents and publishers (British, American, and Colonial), of authors' and artists' societies and clubs, press-cutting agencies, and so forth. New features this year are an article on kinema-play writing, with a detailed list of kinema companies and their requirements, and also an article on press photography. There is also a ruled register for contributions sent out by writers or artists to periodicals.

The third class of reference handbooks—the biographical—is represented in the first place by the now indispensable *Who's Who* (London: Adam and Charles Black. 1914. Price 15*s.* net), which remains unique as an annual biographical dictionary of social celebrities and workers in all spheres of public activity. The book is now too well known to need either description or praise, and it is sufficient to say that the present (the sixty-sixth) issue contains 25,000 concise biographies comprised in 2314 pages.——The 1914 edition of *Who's Who in Science* (*International*) (London: J. and A. Churchill. Pp. 662. Price 10*s.* net) continues to show increasing comprehensiveness and completeness. The number of names has now risen to over 9000, of which not more than one-fourth are British, thus showing the international character of the work. The list of the world's universities, though still lacking as regards South and Central America, has been amplified by the addition of 104 universities and technical colleges, including the major portion of those ancient or renowned universities whose omission in 1913 caused us to comment on this feature last year. Nearly a dozen are added for the United States and Canada. The list of the world's learned societies has been increased from 56 to 64 pages.—— The *Medical Who's Who, 1914* (London and Counties Press Association. Pp. 812. Price 10*s.* 6*d.* net), is this year increased in size by the addition of a large number of names. Evidently the prejudice aroused on its first appearance, which was based on the idea that it was to be a kind of "select"—and therefore invidious—medical directory, is dying out with the removal of that misapprehension. A form requesting the necessary particulars was sent out to every practitioner on the Medical Register of Great Britain and Ireland. ——*Whitaker's Peerage, Baronetage, Knightage, and Companionage, 1914* (London: Whitaker. Pp. 867. Price 5*s.* net), is a useful directory of people of titular distinction. A feature of the new edition is the use of italics to distinguish between those entitled by birth or marriage to the prefix "Hon." and the increasingly large number of persons who have acquired by public service the right to use the distinction.

FOREIGN UNIVERSITY INTELLIGENCE.—*Halle:* Dr. Härtel has been recognised as *privat-docent* of Surgery.—*Innsbruck:* Dr. A. Steyrer, professor in Greifswald, has been appointed Professor of Clinical Medicine, in succession to Dr. Schmidt.—*Naples:* Dr. Carlo Martelli has been recognised as *privat-docent* of Pathological Anatomy.—*Prague (Bohemian University):* Dr. K. Vymola, *privat-docent* of otology and laryngology, has been granted the title of Extraordinary Professor.—*Rome:* Dr. Francesco de Marchio has been recognised as *privat-docent* of Pharmacology and Toxicology.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce for publication the following, among other, new books and editions: "Materia Medica, Pharmacy, Pharmacology, and Therapeutics," by Dr. W. Hale White; thirteenth edition, 6*s.* 6*d.* net. "Elementary Practical Chemistry," Part I., by Frank Clowes and J. Bernard Coleman; sixth edition, with 76 illustrations. "Modern Steel Analysis," by J. A. Pickard, Carnegie Research Scholar of the Iron and Steel Institute. "The Story of Plant Life in the British Isles," by A. R. Horwood.

HAM GREEN SANATORIUM, BRISTOL. — The superintendent, Dr. B. A. I. Peters, has published his first annual report. This sanatorium was set up for the treatment of tuberculosis under the National Insurance Act; 99 persons have been admitted, only 10 of whom were males. The discharged patients number 72; in 30 of these the disease was early, in 20 it was moderately advanced, and in 21 advanced. The remaining case was one of surgical tuberculosis. Of the first class all were fit to resume work, and the same is claimed for 15 of the second group. Even in the third group it is reported that 11 were fit for light work. Graduated exercises, tuberculin, and continuous inhalations were among the methods of treatment employed.

THE LANCET.

LONDON: SATURDAY, DECEMBER 27, 1913.

THE ANNUS MEDICUS 1913.

WHILE year by year it becomes increasingly difficult to know exactly what to include or what to exclude in any attempt to summarise the medical events of 12 months, we find that this annual *résumé*, within the limits which we are enforced to impose upon it, is of such genuine service to many of our readers that we are glad to be publishing it as heretofore. The outstanding occurrence of the year has been the International Medical Congress, held in London, and it will be observed that under various headings reference is made in the following columns to the most important pieces of new work and the most striking evidence of scientific progress which marked a thoroughly successful meeting. The chapter which we now add to the abbreviated history of medicine, that has been compiled in these pages and in this form for some 50 years, lacks features which were present in certain of its predecessors, but others have been added in their place, where the general subjects seemed to us to demand the attention. For one great lesson borne in on us when compiling the Annus Medicus is that the highly important things of one year may become mere details in another.

MEDICINE.

Tuberculosis.

The final report of the Departmental Committee on Tuberculosis was published in March of this year, and contains much material for study and reflection. Since the publication of the Interim Report the Government has decided to place at the disposal of the Local Government Boards, and in the case of Wales at the disposal of the Welsh Insurance Commissioners, a sum of money representing approximately half the estimated cost of treating non-insured persons, as well as the dependents of insured persons. The National Insurance Act made no provision for uninsured persons, while the omission of a section of the population from the national scheme for the treatment of tuberculous persons endangered the success of the whole endeavour. This decision of the Government has closed a dangerous gap in our sanitary defences. A second change in the administration of sanatorium benefit was the granting by the Chancellor of the Exchequer of the "tuberculosis sixpence," to be paid as a capitation grant on all insured persons to the general practitioner in return for domiciliary treatment. One of the most interesting features of the report is the formulation by the Committee of a plan for a permanent bureau under the auspices of which a comprehensive scheme of research could be carried on. The Committee were of opinion that some workers of proved and exceptional ability should be enabled to devote their whole time to research work, and should be given a definite and adequate salary and be entitled to a pension.

On Feb. 1st the Notification and Treatment of Tuberculosis Order of Dec. 19th, 1912, came into effect. Every medical practitioner is now required to make a "primary" notification of tuberculosis to the medical officer of health of the sanitary district in which the patient lives, in any case in which he diagnoses tuberculosis. All forms of the disease must be notified, the only specified exception being tuberculosis the evidence of which is derived solely from the tuberculin tests. The compulsory notification of tuberculosis in England and Wales may now be regarded as completely provided for by the new Regulations. It is based on the assumption that its adoption is in the interests of the tuberculous patients themselves, and to the advantage of preventive medicine and national statistics.

The organisation in London of the treatment of tuberculosis is still in an unsatisfactory condition. The Public Health Committee of the London County Council and the Local Government Board are still considering how the "sanatorium treatment" can best be administered, and some time seems likely to elapse before the scheme is in full working order. We have already expressed the opinion that as far as possible the large general and special hospitals should be employed. The advantages they can offer in the way of an experienced staff, beds for observation cases, special departments, and clinical laboratories are far in excess of any provisions that could be made by the local authorities in the shape of new dispensaries, with a limited staff.

At the Fifth Annual Conference of the National Association for the Prevention of Consumption and other forms of Tuberculosis, held in London on August 4th and 5th, some valuable discussions took place. Particular interest attached to the remarks on the use of tuberculin; owing to the long experience which the various speakers had had of the remedy, their opinions are worthy of the greatest attention and respect. With regard to the diagnostic value of tuberculin there was little difference of opinion, the main objection lying in the fact that tuberculous infection is very common, and the test in whatever form it may be used does not help to distinguish between active and arrested or healed disease. Professor SAHLI was still more emphatic, and maintained that the use of tuberculin for diagnostic purposes ought to be condemned; it was unreliable, both positively and negatively. The opinions expressed as to the therapeutic value of tuberculin were guarded, and on the whole were not altogether favourable to the use of the remedy, but there are many observers who would probably support the opinion expressed by Dr. HECTOR MACKENZIE that the only new form of treatment with any good claim to be a specific which has been brought forward during the last quarter of a century is tuberculin, but it must be administered in a careful and scientific manner, for it is a potent agent for evil as well as for good.

At the same conference Sir R. W. PHILIP spoke on the need for coördination of antituberculous measures. He pleaded for a central administration from which the necessary treatment of patients can be recommended—domiciliary, dispensary, hospital or sanatorium. The principal officers of such an

organisation must be chosen from those who have had an extensive practical experience of tuberculosis derived from many years of observation.

Typhoid Fever.

The Antityphoid Committee was appointed in 1904 by the Army Council, having as its object "to investigate the practical prophylactic and therapeutical value of current methods of immunisation against enteric fever." The greater part of the experimental work has been published in the *Journal of the Royal Army Medical Corps* and the *Journal of the Royal Institute of Public Health*, and has received notice in the columns of THE LANCET, and in the report the definite conclusions alone were collated, freed from technical detail, while the publication of the report was delayed to await the due accumulation of statistical evidence, which could only be obtained from regiments sent on foreign service. Amongst the conclusions arrived at by the Committee were the following: The development of immunity against the typhoid bacillus, as indicated by quantitative investigation of the various antibodies produced, was exhaustively studied both in man and animals. Vaccines made by a variety of methods were compared, but none were found to possess material advantage over that of Sir A. E. WRIGHT, provided the temperature employed for sterilisation be reduced to 53° C. A large number of methods which had been suggested for the standardisation of vaccines were critically examined, and the enumeration of the number of bacteria in a given volume of vaccine was adopted as the most accurate and convenient. The keeping qualities of the vaccine at various temperatures and under practical conditions, such as a voyage through the tropics, were examined. Vaccines three months old were found to be efficient, but serious deterioration in immunising value was apparent in those which had been kept six months or upwards. The histories, as regards typhoid fever, of 19,314 soldiers, whose average period of service abroad was 20 months, were carefully followed, and every precaution possible was taken to verify the diagnosis bacteriologically. Of this number 10,378 were inoculated and 8936 not inoculated. The case-incidence of typhoid fever among the inoculated was 5·39 per 1000, and among the non-inoculated 30·4 per 1000. Finally, the committee unanimously recommended that every measure which might be considered practicable should be employed to extend the practice of antityphoid inoculation in the army. In the opinion of the committee its universal application is desirable. They added that research work on preventive inoculation against typhoid fever, a subject of special importance to the army, should be continued.

At a meeting of the Académie de Médecine of Paris Dr. H. VINCENT reported some remarkable results from antityphoid vaccination. Dr. ALDO CASTELLANI, director, Government Clinic for Tropical Diseases, Colombo, Ceylon, read a paper entitled, "Typhoid and Paratyphoid Vaccination with Live Attenuated Vaccines" at a meeting of the Society of Tropical Medicine held on Dec. 22nd, 1912, the communication being published in the early part of this year. As a result of his investigations he maintained that the use of live attenuated vaccines prepared according to his methods is attended with no harm, and that such vaccine in the lower animals, and probably in man also, gives rise to a higher degree of immunisation than is obtainable with dead vaccines.

Tetanus.

The number of cases of tetanus of any severity that recover is small. The case recorded by Dr. OLIVER ATKEY in our columns of a boy, aged 19, who suffered from a severe attack of the disease and recovered is therefore of interest. He was treated by intravenous injections of paraldehyde and copious injections of normal saline solution. The special advantages of this method of treatment appear to be: 1. The anæsthesia is induced with extreme rapidity. Within a few seconds from the introduction of the needle the muscles become relaxed, and no further pain is experienced. 2. The drug not only acts as an anæsthetic, but also as a hypnotic, and after the period of definite hypnosis has elapsed there still remains a period of relative muscular relaxation lasting several hours. The pain caused by the introduction of the needle is so momentary that it need hardly be reckoned with. A muscular spasm is of necessity caused, but it is almost at once relieved by the relaxing effect of the paraldehyde. On two occasions, however, owing to failure to introduce the needle easily, chloroform was resorted to to enable the needle to be introduced.

Poliomyelitis.

Dr. JAMES MCINTOSH and Dr. HUBERT TURNBULL published an interesting article giving an account of their investigations in reference to the transmission to monkeys of virus obtained from English cases of poliomyelitis.

Dr. SIMON FLEXNER'S brilliant researches on poliomyelitis have been carried an important step further. The subject is dealt with in detail in the Section of Neurology.

Rabies.

At a demonstration given at the Royal Society of Medicineon Oct. 20th, Dr. HIDEYO NOGUCHI showed various stages in the virus of rabies. He said that he was uncertain whether the changes observed represented sporulation, or segmentation, or degeneration. He referred to NEGRI'S observations and showed lantern slides indicating the form of parasites described by that observer. These bodies had been observed in the brains of dogs suffering from rabies; in rabbits these bodies had not been demonstrated, but he (Dr. NOGUCHI) had observed numerous granules. He then referred to the "sporulation" forms found in cultures of the virus of rabies, and by means of lantern slides illustrated the increase in size which these forms underwent in artificial culture media, until finally these bodies broke up into a large number of "granules" similar in appearance to those he had previously described.

Plague.

In discussing the case of a boy, an apprentice on a grain ship that arrived in the Tyne from Rosario (River Plate), who died from plague, Dr. W. J. TULLOCH drew attention to the many difficulties which exist in recognising cases of plague which may arrive on our shores on healthy ships from foreign ports not known to be infected. He urged the examination by blood culture as a method to be adopted in all doubtful cases, and if used as a routine procedure in the indefinite febrile illnesses which occur on board ships it would, he contended, be found a valuable aid to diagnosis. In the case described by Dr. TULLOCH the strain of the plague infection was peculiar, since two other cases of illness had previously occurred on the same vessel

while it was lying in the Elbe. The first case was diagnosed as influenza, but proved fatal on the third day; the second case had symptoms suggestive of enteric fever, the illness lasting 23 days before it terminated fatally. Post-mortem examination with bacteriological investigation of material ultimately established a diagnosis of plague in each case. The ship carried four apprentices, who occupied a cabin at the stern of the vessel far removed from the quarters of the crew. The lads had a pet rabbit which was infested by fleas; it died while the ship was in the Elbe. It was conjectured that infected rats came on board at Rosario with the cargo, and that towards the end of the voyage the rabbit contracted the disease from the rats and conveyed it to three out of the four boys, who were accustomed to play daily with their infected pet. The strain of infection, though peculiar in its manifestations, was nevertheless of a virulent kind, as all three apprentices died from it.

The Pathogenicity and Virulence of Bacteria.

On Jan. 25th we published a preliminary communication on the Pathogenicity and Virulence of Bacteria from the Bacteriological Laboratory of University College Hospital, by Dr. F. H. THIELE and Dr. DENNIS EMBLETON. As much of the work on which the paper was based had not been published the authors briefly reviewed some of the results which had been obtained by other observers. They then gave an account of their own investigations, and conclude from a number of experiments that the pathogenicity of bacteria depends on the presence in the susceptible animal of a ferment capable of producing lysis of the proteids of the bacterial body; the mechanism of the cellular defences of the body is hindered by the setting free of antiphagocytic substances, with the result that the bacteria multiply to numbers to cause disease or death. Thus if the bacterium is not acted upon by ferments, it remains innocuous (saprophytes). If the ferment action is able to split off from the bacterium toxic substances sufficient in amount to inhibit phagocytosis the animal becomes infected (parasites). Further, Dr. THIELE and Dr. EMBLETON believe that if the ferment action is sufficiently active and rapid the changes in the bacterial protoplasm may advance to such an extent that even the toxic products of degeneration are destroyed; in this event no aggressive substances are liberated, and phagocytosis can proceed unhindered. With regard to virulence, these authors believe that it depends upon the power of the bacterium to exude around itself a zone of its cytoplasm which remains in position and acts as a protective shield. This shield, which is in some cases a visible capsule, protects the bacterium against the action of specific ferments, and also resists phagocytosis by virtue of its aggressive property. They hold, then, that pathogenicity is due to the virulence of the bacterium and the relative activity of the ferment to the bacterium. Immunity is due to ferment action and phagocytosis.

The Specific Differences among Bacteria.

In delivering the Presidential Address before the Pathological Section of the Royal Society of Medicine Dr. F. W. ANDREWES took as his subject the Nature and Degree of Specific Differences amongst Bacteria. For a considerable number of years he has carried out researches in collaboration with Dr. M. H. GORDON and Dr. T. J. HORDER, which have been especially concerned with the various bacteria as different species. He pointed out that the term "species," at least among certain groups of bacteria, had become an extremely elusive one to define in spite of constantly increasing refinements in the methods of study. He further drew attention to the naturalist's criteria of species, and remarked that when the bacteriologist attempts to apply such criteria as these he is baffled. By species the naturalist means a freely interbreeding group of individuals derived from a common ancestor. He recognises and defines what he means by a species according to several criteria—morphological characters, capacity or incapacity for interbreeding, known descent from a common ancestor, and in certain cases geographical distribution. As Dr. ANDREWES pointed out, the bacteriologist is handicapped in the investigation of the various species of bacteria by the fact that the only one of these criteria available to him is the study of the morphological characters. The absence of sexual reproduction affords one reason for the extreme variability of bacteria; in the second place, as the lecturer said, the inordinate rapidity with which bacteria multiply allows the effects of environment to become apparent in a very short space of time. It is possible that such effects are stamped with greater readiness on the sensitive and labile protoplasm of unicellular organisms than on the more complex structure of higher types. In any case, he remarked, natural selection must act with greater intensity upon creatures which can pass through 20 or 30 generations in a day than upon those which reproduce their kind only once or twice a year. Dr. ANDREWES insisted that it is only with extreme caution that such characters as pathogenicity or metabolic capacity can be regarded as of specific value. Passing to the question of specific types of bacteria, Dr. ANDREWES referred especially to the much-discussed question of the identity of the various strains and remarked that in some bacterial groups rigid specific limits have actually no existence. We may leave off quarrelling as to the specific value of fermentation tests and serological reactions, and bend our minds to doing the best we can with the mass of related forms presented by dominant bacterial genera. Nor is the task of classification a hopeless one, he thought, if it be approached in the right spirit and with a due apprehension of the real state of affairs. The group of streptococci received especial consideration. He held them to be a labile group from which types are emerging, which can be recognised by suitable methods. With reference to the future, he looked to a chemical solution of many at present baffling problems. He mentioned two phenomena which are probably chemical or physico-chemical reactions—namely, agglutination and precipitation of bacteria—and thought that they will receive their true elucidation at the hands of the experimental chemist.

Sensitised Vaccines.

In a paper read before the Therapeutical Section of the Royal Society of Medicine Dr. M. H. GORDON made a notable contribution to the treatment of certain bacterial infections by sensitised vaccines. He pointed out the disadvantages of the ordinary specific methods of treatment by immune serums and vaccines respectively. Immune serums not only sometimes give rise to anaphylactic shock or serum sickness, but also with certain notable exceptions they have proved disappointing in practice, while with vaccines the well-known negative phase constitutes a risk which is by no means negligible

in some cases. He gave brief records of a number of cases of streptococcal infection treated by means of sensitised vaccines, and to judge from the careful summary of his results they are such as to be distinctly encouraging. He suggested that the method may have a great future, not only as a scheme of treatment of infections already established, but as a prophylactic agent in epidemics.

Alimentary Toxæmia.

A prolonged and interesting discussion lasting over several meetings took place on the subject of alimentary toxæmia at the Royal Society of Medicine. The subject was approached from many points of view—namely, from those of medicine, surgery, anatomy, pathology, chemistry, and of special departments of practice, such as ophthalmology, dermatology, and dentistry. Throughout a high level was maintained. The reports of the discussion have now been published separately, and show that there is still much to be learned about the pathology, symptomatology, and treatment of the condition. The discussion will tend to promote further research, both clinical and pathological, and will serve to lessen the tendency to invoke alimentary toxæmia as an explanation for various obscure conditions upon insufficient evidence.

Arterio-sclerosis and High Tension.

Discussions took place at the Medical Society of London and at the Section of Balneology and Climatology of the Royal Society of Medicine which raised many points in connexion with arterio-sclerosis and high tension. Dr. F. DE HAVILLAND HALL, who introduced the subject at the Medical Society of London, after reviewing the various conditions causing arterio-sclerotic changes in the blood-vessels, laid stress on the importance of regulation of the diet and relieving mental strain, and he considered that auto-intoxication was a powerful etiological factor. Dr. H. A. DES VŒUX, in a humorous and forcible speech, declared that in many cases the existence of high tension, even if it was proved, was of little pathological significance, and deplored the condemnation of such patients to invalidism. Dr. A. MANTLE, in the discussion at the Royal Society of Medicine, said that super-normal arterial pressure is not itself a primary condition to be attacked or controlled as such. The majority of those who took part in these discussions were of opinion that the nitrites, iodide of potassium, and other drugs used for the purpose of lowering blood tension are only temporary in their action and must be given with caution.

Climatology in Medicine.

In delivering the Samuel Hyde Memorial Lectures on the Place of Climatology in Medicine Dr. WILLIAM GORDON maintained that climatology should be more systematically studied and taught than it is at present. He alluded to what he termed "the principle of approximate isolation of influences." By such approximate isolation he meant not merely the happy-go-lucky elimination of this or that influence in the investigation of a third, but the systematic enumeration of all the known influences which seem to affect the field of inquiry besides the influence in question, and their successive elimination from the problem in one way or another, so far as that is possible. He illustrated this principle by dwelling on the influence of rain-bearing winds on the prevalence of phthisis and pointed out the fallacies which had arisen by neglect of this principle in developing the high altitude theory of phthisis immunity. After a careful survey of the evidence that had been brought forward in support of this theory he expressed the opinion that no evidence of any value exists in favour of this theory.

The Official Medical Lectures of the Year.

We published in our columns most of the lectures delivered before the Royal College of Physicians of London and many delivered before other learned bodies. Dr. A. J. JEX-BLAKE delivered the Goulstonian lectures on Death by Lightning and Electric Currents. Dr. T. R. GLYNN was the Bradshaw lecturer, choosing for his subject Hysteria in some of its Prospects. He alluded particularly to Charcot's stigmata, and to the precautions to be exercised in examining patients suspected of being hysterical. In men, said the lecturer, the fragmentary hysterical paroxysms—transient giddiness, dimness of sight, and confusion—were as valuable as indications of hysteria as were the more pronounced fits in women; he had found a history of such attacks in four-fifths of men suffering from traumatic hysteria. He then considered hysteria as he had met with it in association with epilepsy, chorea, chlorosis, Graves's disease, stomach disorders, diseases of the heart and nervous system. The Milroy lectures were delivered by Major ROBERT MCCARRISON, I.M.S., the subject being the Etiology of Endemic Goitre. He considered this condition to be due to a living excitant or *contagium vivum*, and that the various conditions which have hitherto been regarded as causing the disease are such as favour the growth, development, and ingestion of this causal organism.

Dr. F. DE HAVILLAND HALL delivered the Lumleian lectures, taking as his theme Intra-thoracic Aneurysm. He considered at length the various aspects of the disease from the points of view of etiology, symptomatology, diagnosis, and treatment. The Oliver-Sharpey lectures were in the hands of Dr. A. WALLER, the subject being the Electrical Action of the Human Heart. Dr. J. MITCHELL BRUCE was the Harveian orator, his remarks being directed to the Influence of Harvey's Work in the Development of the Doctrine of Infection and Immunity.

Professor C. J. MARTIN, in delivering the Horace Dobell lectures at the Royal College of Physicians at the end of last year (although the lectures were not published until the commencement of the present year), drew attention to many points in connexion with insects as carriers of bacterial infection.

The Seventeenth International Congress of Medicine.

Medicine proper was, of course, very fully represented at the International Congress. In the Section of Medicine a number of important papers were read and discussed, and were reported at some length in our columns. The Address in Medicine was delivered by Professor A. CHAUFFARD, professor of clinical medicine in the University of Paris. He chose as his subject Medical Prognosis, its Methods, its Evolution, and its Limitations. He outlined the history of clinical medicine with great exactness, and even with thoroughness, although his remarks only lasted an hour. Regarding medicine from a clinical point of view, he ranged from the Hippocratic era down to the latest discoveries in bacillary and amœbic infection, and between these two extremes showed how medicine had been passing steadily from an art to a science, and how day by day fresh knowledge was being obtained.

He dwelt on the great change in medical thought which the science of physiology had brought about, and he maintained that the clinical physician, by knowledge of physiology and with a system of pathology founded on that knowledge, is now able to treat many conditions with much the same certainty that the surgeon can show when dealing with an obvious injury. Professor PAUL EHRLICH'S general Address in Pathology contained much of direct interest to the physician. He gave an excellent account of the way in which the latest remedies act against those microscopic foes which threaten the life and health alike of men and animals. Before proceeding to discuss the principle of fixation in chemotherapy, he pointed out that gradually we have come to learn something of the complex method by which the animal defends itself against the assaults of micro-organisms; and our knowledge, incomplete though it may be, has enabled us to devise methods of aiding the efforts of the body to get rid of the invading germs.

The definite association of modern medicine with the latest researches in genetics was emphasised in the general Address on Heredity by Professor WILLIAM BATESON, President-elect of the British Association. While able only to give a bird's-eye view of the interesting position which has now been reached, he added some valuable indications as to the far-reaching direction in which the studies comprehensively described under the title of heredity are being carried on.

The Pathology of Heart Failure was the subject of a discussion in the Section of Medicine. It was opened by Professor H. VAQUEZ, of Paris, who gave an account of the various methods of clinical investigation that were of value when heart failure was to be expected or diagnosed. Professor W. T. RITCHIE in his remarks drew attention to "auricular flutter," a condition akin to the auricular fibrillation that had been brought so prominently to the fore by the electrocardiograph.

Dr. G. DOCK, of St. Louis, opened a discussion on Diabetes Mellitus, and went fully into the different views that have been published in the hope of clearing up its etiology.

Professor C. VON NOORDEN presented a diagrammatic scheme in which the control of the glycogenic function of the liver was set out. The pancreas was the organ that tended to keep the consumption of sugar down; the chromaffin system (or, to mention its chief constituent, the suprarenal gland) tried to increase its consumption. But the pancreas was in turn controlled by the thyroid gland, the parathyroids, and the hypophysis, while the chromaffin system was under the control of the central nervous system. All these controls, except that of the central nervous system were exercised by the medium of the secretions of the various glands concerned, conveyed about the body by the blood-stream. When the blood contained an amount of glucose above the normal, this was due either to the weakening of the inhibiting power of the pancreas or to the increase in the augmenting power of the chromaffin system.

In the Section of Therapeutics a discussion took place on the Comparative Value of Cardiac Remedies. It was opened by Professor R. GOTTLIEB, of Heidelberg, who pointed out that, in order to explain the action of digitalis and other cardiac drugs and to construct a rational plan of treatment, the results of different methods of investigation such as those of clinical observation and pharmacological experiments must be coördinated and brought into line.

Professor THEODORE C. JANEWAY, of New York, presented an interesting report dealing more particularly with his experience in the clinical use of cardiac remedies from the standpoint of their efficiency in combating definite perversions of function. In his opinion the best results from digitalis were obtained in a special group of cases which he described—viz., cases of well compensated mitral disease—in which auricular fibrillation with great tachycardia set in acutely. Failure to obtain satisfactory results from digitalis therapy in suitable cases was evidence of an inefficient preparation, insufficient dosage, or an improper mode of administration.

In the Section of Bacteriology an instructive discussion on "filter passers" was opened by Professor F. LOEFFLER, who said that since he and FROSCH showed in 1898 that the virus of foot-and-mouth disease passed through filters a large series of diseases had been attributed to "filter passers." Amongst these might be mentioned yellow fever, dengue, pappataci fever, poliomyelitis, and infective pleuro-pneumonia of cattle. Recently it had been asserted that the infective agents of scarlet fever, measles, and typhus fever also belonged to this group. He urged that, in view of the great importance of filter passers in the etiology of disease, laboratories should be devoted to the study in all countries. Sir JOHN MCFADYEAN said that the demonstration of invisible viruses marked a new epoch.

SURGERY.

The great event of the year in surgery, as in other branches of medical science, has undoubtedly been the London meeting of the International Medical Congress. Not only were many important subjects discussed, but the presence of many eminent surgeons from the colonies and from foreign countries gave the meeting an importance which it would not otherwise have possessed.

Malignant Diseases of Large Intestine.

There were several set discussions. The first of these was on the Operative Treatment of Malignant Diseases of the Large Intestine, excluding the Rectum. It was opened by Professor R. BASTIANELLI. He agreed that in cases of obstruction it was wiser not to make an attempt at resection of the growth until the obstruction had been removed. He favoured a cæcal opening for the drainage of the obstructed bowel; the opening should be large, and yet it could be easily closed when the time came. It was probable, he considered, that in future we should be inclined to remove more of the bowel than at present. As to the results, since 1900 he had had 84 cases with a mortality of 60 per cent., but since 1905 the mortality had been only 4·5 per cent.—that is, only 2 cases had proved fatal out of 44. He had also collected 739 cases, and in these the death-rate had been 26 per cent.

Professor KÖRTE, who followed, also held that in acute obstruction the best treatment was to perform colotomy, and to postpone to a later operation the removal of the growth, and even in chronic obstruction he thought that the same two-stage operation was the best. Dr. A. L. SORESI contributed to the discussion by describing a new method of intestinal anastomosis which he had invented and which saved time. Mr. H. J. PATERSON laid stress on the importance of exploring the abdomen thoroughly in all cases in which there was a diminution in the hydrochloric acid of the stomach, and thus

malignant disease of the bowel might be discovered at a very early stage. Sir FREDERIC EVE had collected the statistics of all the cases operated on at the London Hospital from 1901 to 1911. Of 127 in which colotomy was done the mortality was 54 per cent.; immediate resection was performed in 95 cases with a mortality of 48·4 per cent., while with secondary resection the death-rate was 38·8 per cent. Professor KRYNSKI was in favour of immediate resection if the indications were favourable.

Early Renal and Vesical Tuberculosis.

The second general discussion dealt with the Diagnosis and Treatment of Early Renal and Vesical Tuberculosis. It was opened by Professor VICTOR ROCHET. He expressed the opinion that it was not advisable to operate on those early cases of tuberculosis of the kidney, in which the only proof of the presence of tuberculosis was the discovery of tubercle bacilli in the urine; it was well to wait for pyuria, for in earlier stages general treatment was indicated and not local treatment. When both kidneys were affected there was no indication for surgical treatment unless there was evidence that in one kidney there was some severe lesion threatening life. The bladder was rarely affected with tuberculosis primarily, and when the disease there was secondary the primary disease was in the kidney or in the genital organs in the male, and then the primary disease should be treated. In the extremely rare cases in which the bladder is affected primarily general treatment is indicated if the disease is early, and only when the bladder disease is severe is local treatment indicated. Dr. HANS WILDBOLZ held that really early tuberculosis of the kidney is not recognisable, and when it is recognised the disease is already somewhat far advanced. As soon as tuberculosis of one kidney could be diagnosed and the other was healthy then removal of the affected organ as soon as possible was the best treatment. Mr. C. A. LEEDHAM-GREEN thought that it was very difficult to estimate the stage of the disease, and that it was wise not to be in too much of a hurry to operate. Dr. G. VAN HOUTUM believed in the local treatment of tuberculosis of the bladder. Professor ROVSING mentioned that it was very rare to see tuberculosis of the kidney in an early stage, and practically it was only when a man was examined for life insurance that a really early tuberculosis of the kidney was discovered. He had a very small opinion of the value of tuberculin in renal or vesical tuberculosis; on the other hand, Professor E. HURRY FENWICK thought highly of tuberculin, perhaps hardly as a curative agent, but rather as a tonic. He considered that it was possible to recognise tuberculosis of the kidney as early as the third week. Early removal of the kidney was the best treatment, and it had a mortality of only 8 per cent.

Tumours of the Brain.

The third set discussion of the Section of Surgery was held in conjunction with the Section of Neurology; it dealt with "The Treatment of Tumours of the Brain and the Indications for Operation." It was opened by Professor BRUNS. He pointed out that there were two operations for brain tumours, removal and decompression, and the latter might be done intentionally or it might be found when the brain was exposed that the tumour could not be removed. The nature of the tumour and its site were points of the greatest importance in estimating the chances of operation. A decompression operation was clearly indicated in those cases in which the exact site of the tumour could not be ascertained and the symptoms were severe. The subject was discussed by many speakers, and there was certainly a majority who held that the cases in which a tumour could be completely and permanently removed were very few, and that the mortality from the operation must be large. Professor HARVEY CUSHING believed that the cases in which a perfect restoration of the general health was obtained were very few in number, perhaps 5 per cent. Sir VICTOR HORSLEY held that the results of the surgery of brain tumours could only be improved by the earlier diagnosis of the condition. So long as the text-books continued to say that headache, vomiting, and optic neuritis were the signs of cerebral tumour, so long would the cases come to the surgeon at too late a stage. These three classical signs generally appeared at a time when the growth was passing beyond the reach of the surgeon. Professor H. CLAUDE held that if decompression was to do any real good it should be performed early. Sir WILLIAM MACEWEN also laid stress on the need for early diagnosis if operation was to do any good.

Surgery of the Arterial System.

A fourth discussion of importance was that on "The Surgery of the Arterial System," which was opened by Professor RUDOLPH MATAS, and his speech consisted mainly of an account of the operations on aneurysm which he had devised. Of 225 cases operated on by one or other of his methods 206 were successful; in four gangrene occurred. In all the four cases in which aneurysms of the abdominal aorta were treated death followed. Mr. C. A. BALLANCE considered endo-aneurysmorrhaphy a very great advance. Dr. ERNST JEGER reported a large number of experiments which he had performed on animals; he had achieved a large measure of success in the suture of vessels. He had been able to show that in animals it was possible to unite the innominate artery to a branch of the pulmonary artery, so that a part of the lung was supplied with arterial blood. Dr. CHARLES GOODMAN pointed out that thrombosis was the most important complication of blood-vessel surgery, and he insisted on the need of isolating the operation field from the rest of the wound. Dr. V. SOUBBOTITCH gave an interesting account of the vascular surgery met with in the recent Balkan wars. Dr. N. A. DOBROWOLSKUJA showed by a series of specimens how excellent may be the results of vessel-suture. Dr. A. CHIASSERINI had had success in animals in replacing a portion of the abdominal aorta by pieces of fascia.

Other Subjects at the International Congress.

In the discussion on intrathoracic surgery which was opened by Professor F. SAUERBRUCH it was clear that the tendency was to replace the more elaborate methods of maintaining the intrapulmonary pressure by some form of intratracheal insufflation. In this discussion the most striking occurrence was a demonstration given by Sir WILLIAM MACEWEN that the lung was not maintained in contact with the chest wall by atmospheric pressure, for he showed that they still adhered together, even when the atmospheric pressure was reduced to two or three millimetres of mercury.

A large number of important papers were read in the surgical section, and it is difficult to say which were those of the greatest interest, but we may

refer to Dr. RUSSELL S. FOWLER'S account of the use of the position which is called by his name and employed for the treatment of peritonitis, and the paper by Dr. CHARLES GOODMAN on Arterio-venous Anastomosis for impending gangrene. The results so far obtained appear to show that the method can prevent gangrene if the operation is not left too late.

Appendicitis.

Mr. EDMUND OWEN started a correspondence on the time to operate in appendicitis. by the publication of a paper which he had read at the Medical Society of London. The paper was entitled "Appendicitis, a Plea for Immediate Operation," and put forward with great eloquence that there should be no delay in operating on a patient in whom appendicitis has been diagnosed. Mr. OWEN advanced reasons for this immediate action; he showed that the surgeon can never tell the exact condition of the appendix, that it may indeed be a mild inflammation of the appendix from which the patient may recover with a few days' or weeks' rest in bed; but it may, on the other hand, be a case where the appendix is ready to burst and to flood the peritoneal cavity with very septic pus, and nothing in the signs or symptoms can enable the surgeon to distinguish with certainty the one from the other. He claimed that immediate operation would save many lives that would be otherwise lost; that the policy of procrastination must lead to many deaths which could have been avoided; while in those cases where mere rest would have led to an arrest of the inflammation the patient had been saved once and for all the risks and dangers of further attacks of the disease. In politics the motto "Wait and see" might suffice; for the surgeon in a case which has been diagnosed as appendicitis the motto should be "Look and see." It is not surprising that an address expressing sentiments such as these should evoke a number of replies. At the meeting of the Medical Society indeed there was unanimity, but that was merely because opponents were absent.

In the subsequent discussion in THE LANCET there was among some of those who wrote a tendency to advocate a waiting policy in all cases which had passed the second day, as the statistics appear to show that operation from this day to about the sixth or seventh day is accompanied by a large mortality. The discussion was of great interest, and though it may be said that not one of the controversialists was convinced by the arguments of his opponents, yet it is certain that the number of those who advocate a waiting policy is steadily diminishing. More and more every year those who have previously adopted the watching method of treating cases of acute appendicitis which have passed the first two or three days are becoming advocates of the immediate operation.

Traumatic Appendicitis.

Cases of appendicitis attributed to injury are rare, though some 100 such have been recorded. The relative frequency has been variously estimated from 0·8 per cent. to 8 per cent., and this difference is probably due to the difficulty of estimating the relation of cause and effect. Only one writer, SPRENGEL, has denied that trauma can ever be a cause. A striking case has been reported by Mr. J. DANIEL. A woman, aged 18 years, was kicked in the right iliac fossa by her husband, and the pain, though severe, passed off. A week later she felt acute abdominal pain, especially in the right iliac fossa, and she was compelled to stay in bed; vomiting and constipation were present. She continued in this state with remissions for more than three weeks, and then was admitted to hospital, when her temperature was 103·5°; there was resistance over the right iliac fossa, and appendicitis was diagnosed. The temperature fell to normal with medical treatment, and 12 days later an "interval operation" was performed. The appendix had many adhesions, but it contained no stercolith. The medico-legal importance of traumatic appendicitis can hardly be over-estimated, for claims may depend upon the view taken as to the origin of the inflammation.

The Black (Pigmented) Appendix.

Mr. W. H. BATTLE has drawn attention to the pigmented form of the appendix, and he has described four cases of the condition. In all of these the pigment was situated in the mucous membrane and the colour was clearly due to iron. The condition has been noticed by several German surgeons, and they also have found iron to be present. Some years ago Dr. G. NEWTON PITT described a case of pigmented bowel in which the pigment was lead sulphide; the patient had been a worker in lead.

Bastedo's Sign of Chronic Appendicitis.

Dr. ARTHUR F. HERTZ has drawn attention to the sign of chronic appendicitis, which was first described by BASTEDO in 1909. The large intestine is slowly inflated with air, by means of a rectal tube and a small pump such as is used in sigmoidoscopy. Then if chronic appendicitis is present pain is felt in the right iliac fossa, and often there is tenderness over McBurney's spot. The test appears to be of some value in chronic ill-defined cases, for when it gives a positive result chronic appendicitis appears always to be present, but a negative result does not appear to be so conclusive.

Wounds of the Abdomen.

Dr. JOHN A. C. MACEWEN has reported a case in which a boy, 10 years old, fell on a spike; he was able to walk home, but four hours later he was removed to the hospital. He was found to have a small punctured wound in the epigastrium, with a little local tenderness, but there was no shock. Soon he vomited, but the vomit contained no blood. A probe entered only a short distance. The right side of the abdomen, however, remained rigid and tender, so an anæsthetic was administered, and it was found with a finger that the wound led into the abdominal cavity. When the abdomen was opened it was seen that the stomach was perforated, both on its anterior and its posterior walls; there was also a wound of the mesocolon, with about a pint of blood in the peritoneal cavity. The perforations were closed and the patient recovered completely.

Rupture of the Spleen.

Major J. W. F. RAIT, I.M.S., has recorded a case of rupture of the spleen, due to a blow received three hours before the patient was admitted into the Calcutta Hospital. There was abdominal dulness and the patient was collapsed. On opening the abdomen much blood escaped, and a rent of the spleen was found near the lower margin; the spleen was removed after ligature of its vessels. An intravenous infusion of saline fluid was given and some hot saline was left in the abdominal cavity. In this case the spleen appears to have been quite normal, though rupture of a malarial spleen is common.

Dr. R. SEHEULT has recorded also a case of

ruptured spleen. A boy, aged 13 years, fell from a height of 16 feet while climbing a tree. He was seen by a doctor, but he was sent home. As the pain continued he was taken late the next day to the hospital. On admission there was some abdominal pain and the abdomen was slightly distended, and there was some diminution of the liver dulness. The urine was drawn off but no blood was present. As the symptoms were not urgent he was kept quiet, with an icebag on the abdomen. The next morning, however, as the pain continued and there was dulness in the flanks, Dr. SEHEULT determined to operate. When the abdomen was opened much dark-coloured blood escaped. The whole of the bowel was examined, but no injury was found; the liver was also found to be intact, but the spleen was seen to be extensively lacerated. The pedicle was clamped and tied. In this case the most remarkable point was the long interval of nearly 48 hours between the infliction of the injury and the removal of the spleen. It is probable that the hæmorrhage was not severe at any moment, or the patient could not have survived.

Mr. WILLMOTT EVANS has reported a case of rupture of the spleen which was complicated with rupture of the liver. A boy, aged 15 years, was run over by a cart, one wheel passing over the abdomen. He was pale but not blanched, and he complained of abdominal pain. He vomited two or three times, and the first vomit contained a little blood. A catheter was passed into the bladder and clear urine was drawn off. There was some dulness in the flanks. A diagnosis of rupture of the spleen was made. When the abdomen was opened near the outer border of the left rectus about two pints of blood escaped and the spleen was found much torn; its vessels were sutured and the spleen was removed. The surface of the liver was then examined with the hand and two tears in it were felt. The wound on the left side of the abdomen was closed and an incision was made on the right side parallel to the margin of the ribs. It was then found that there were three tears in the liver. As the patient was very collapsed the wounds in the liver were packed with aseptic gauze. Three days later the gauze packing was removed and the patient recovered completely and rapidly. The noteworthy point about this case is the successful result after rupture of both spleen and liver.

The Cause of Death in Acute Intestinal Obstruction.

Mr. D. P. D. WILKIE has recorded a number of experiments which he has made on the cause of death after acute obstruction of the bowel. He showed that when the obstruction was high in the bowel the free loss of fluid by vomiting accounted in great part for the symptoms. When the intestine was strangulated his researches indicated that the acute symptoms and the early fatal issue were due mainly to shock and splanchnic paresis, and slightly also to the absorption of toxins from the strangulated loop. The practical conclusions drawn were: (1) that the surgery of intestinal obstruction should be as conservative as possible, and that only on imperative indications should the lumen of the bowel be opened, for the danger of peritonitis is greater than that of absorption toxæmia; and (2) that in all forms of intestinal obstruction great improvement follows copious subcutaneous infusions of saline and dextrose solutions.

Foreign Bodies in the Œsophagus and Air Passages.

Sir STCLAIR THOMSON has reported a very rare and interesting case in which he removed a tooth-plate from the œsophagus after two and a half years. The patient was a man, 22 years old, and during the night he swallowed half of a cracked vulcanite tooth-plate. He felt pain in the throat and a difficulty in swallowing. The pain and difficulty were referred to a particular spot behind the breast bone. As the symptoms persisted he was carefully examined at several hospitals and the X rays were used, but nothing was found and the diagnosis given was neurotic dysphagia. When Sir STCLAIR THOMSON saw him the plate had been seen by direct œsophagoscopy by Dr. IRWIN MOORE, and a skiagram showed the plate, but very faintly. Then under chloroform the plate was seized through a Brünings tube and the tube, forceps, and plate were removed together. The case shows well how such a foreign body may be overlooked; it is also remarkable that so irregular a body should have given rise to comparatively little discomfort, although it had been retained for two and a half years. Mr. GEORGE N. BIGGS had a similar case of some interest. A boy swallowed a piece of rabbit bone, and immediately felt pain about an inch below the cricoid cartilage. Attempts to remove it with a probang failed. When he was seen the next day an œsophagoscope was passed and a swelling was seen on the posterior wall of the œsophagus, and the piece of bone was seen protruding from a small opening from which about a drachm of pus exuded. The bone was removed with forceps and proved to be about an inch long and pointed at both ends. He was fed by enemata for four days, but on the seventh day he had dysphagia and dyspnœa and his temperature was 105°. A swelling was felt externally, and pressure on this made the boy cough up about an ounce of very foul pus. Immediately all the symptoms were relieved, and the boy soon recovered. It is possible that in this case the probang had pushed the piece of bone through the œsophageal wall.

Dr. WILLIAM MILLIGAN gave an interesting post-graduate lecture on œsophagoscopy and bronchoscopy for foreign bodies, and he related a number of cases which showed the value of the method. Similar cases were also recorded of the removal of foreign bodies from the air passages. Mr. W. G. HOWARTH contributed to THE LANCET a paper on the removal of foreign bodies from the larynx and bronchi. In one case a baby, 9 months old, was found to be gasping for breath and an X ray photograph showed a foreign body in the subglottic space. It was readily extracted with a pair of Brünings's forceps, and it proved to be the mouth of a tin trumpet. In another case a man had worn a tracheotomy tube for laryngeal stenosis; a part of the tube was missing, and he mentioned that he had had a cough for some days. A skiagram showed the foreign body in the right main bronchus, whence it was extracted with forceps. In two other cases it was known that a foreign body had passed into the air passages; in one of these the object was a pin, and in the other a hairpin; and in each case the body was lodged in a bronchus. The removal of foreign bodies from the œsophagus and the air passages has become a much simpler matter than even a few years ago, for by Killian's or Brünings's tube they may usually be readily removed.

Mr. THOMAS H. KELLOCK has reported a case in

which he removed a foreign body from the lung. The patient was a boy, 4½ years old, and four days before admission to the hospital he swallowed a shawl pin about 2 inches long. He seemed to be in good health and no abnormal signs were present. A skiagram showed the pin in the right bronchus, though subsequently it slipped down lower. Attempts to remove it through a bronchoscope failed both when the tube was passed through the mouth and when it was passed through a tracheotomy wound. Then when the tracheotomy wound had closed Mr. KELLOCK made an opening through the chest-wall on the right side, forming a window about 3 inches square. The finger could feel the diaphragmatic surface of the right lung, a hard spot was felt there, and a small incision was made over it, and with a litttle trouble the pin was felt and extracted with forceps. The child recovered, though for the first few days it was a little restless.

Fracture of the Neck of the Femur.

Dr. ROYAL WHITMAN has contributed a paper on the method devised by him of treating fracture of the neck of the femur by placing the limb in the position of abduction. He points out that in this fracture the outer fragment is turned forwards and displaced upward, and the adjusting the outer fragment to the inner is accomplished as follows:—The patient is anæsthetised and placed on a sacral support, and then an assistant abducts the sound limb to the anatomical limit so as to demonstrate the normal range, which varies in different persons, and this also serves to fix the pelvis. Then the thigh on the affected side is flexed to disengage the fragments. The hip is then extended and longitudinal traction is made to overcome the shortening. The limb is rotated somewhat inwards and is abducted to the normal limit, as shown by the thigh of the other side. In this position the fractured bone is fixed by a plaster spica, extending down the limb as far as the ankle. The method is ingenious, and it has probably not been employed to the extent which it deserves, though most of the objections brought against it have been theoretical rather than practical.

Hyperextension and "Back-fire" Injuries of the Wrist.

Mr. CUTHBERT S. WALLACE has contributed a paper on the injuries in the neighbourhood of the wrist which result from forcible over-extension of the hand. The lesions produced vary greatly in different cases. In one case there was dislocation of the semilunar, fracture of the neck of the scaphoid, and a vertical fracture of the lower end of the radius, taking off its styloid process. The semilunar bone and the loose piece of the proximal end of the scaphoid were removed. In a second case the whole of the second row of carpal bones was dislocated backwards on to the back of the first row, and in addition the semilunar was dislocated. In a third case the semilunar and pyramidal bones were displaced forwards and upwards. He discussed the mechanism of the production of these fractures, and showed how the angle of flexion affected the result. The injuries of "backfire" were exemplified by two cases; in one the radius was fractured three inches above its lower end, and the upper end of the lower fragment was displaced forwards. In the other case the fracture was of the lower end of the radius; starting about three-quarters of an inch above the tip of the styloid process, it passed inwards and downwards to enter the wrist-joint just external to the radio-ulnar articulation. This latter is the lesion which has been called chauffeur's fracture. There was no displacement.

OBSTETRICS AND GYNÆCOLOGY.

The Ductless Glands and Pelvic Organs.

The ductless glands and their relation to the functions of the pelvic organs have excited a good deal of attention during the past year, and formed the subject of the Arris and Gale lectures at the Royal College of Surgeons given by Dr. W. BLAIR BELL, and also of a discussion at the Section of Obstetrics and Gynæcology of the Royal Society of Medicine introduced by him. The curious part played by the pituitary gland in the production of the so-called "dystrophia adiposo-genitalis," the occurrence of sexual precocity, premature adolescence, and early setting of the body in association with hypertrophy of the cortex of the suprarenal, and the arrest of the body growth accompanying atrophy of the thyroid—all these demonstrate how important a part in metabolism is played by these secretions, and what an intimate relationship they bear to the many problems associated with sexual characteristics and sexual development. Dr. BLAIR BELL'S lectures form a useful summary of our knowledge, which as regards actual facts is very small indeed. Unfortunately, at the present time there is a widespread tendency to attribute all kinds of varying errors of metabolism to disturbances of one or other of the ductless glands when practically nothing is known with any certainty. It is of the utmost importance if our knowledge of this subject is not to be confused by unwarrantable hypotheses that we should accumulate a much larger number of definite and proven facts, and refrain from crude generalisations, however fascinating and apparently illuminating they may be. The investigations required to detect changes in the general metabolism of the body as the result of disease or artificial removal of one or more of the ductless glands are of the highest complexity, and must be carried out in very large series of cases carefully controlled before any definite conclusions can be drawn from them.

Dr. BLAIR BELL holds that any influence the ovary has over the general metabolism is related to, and dependent upon, its primary reproductive functions. He believes that the thyroid, the pituitary, and the adrenals influence the development and preserve the activity and integrity of the genitalia, while the thymus, and possibly the pineal, appear to prevent sexual precocity. He further maintains that all the ductless glands control the metabolism in response to the necessities of the genital functions. When, however, the reproductive glands are removed or atrophy the primary genital functions of the rest of the ductless glands cease, and the rearrangement of the metabolism that follows produces the symptoms which are known as those of the menopause. On the other hand, insufficiency of the thyroid, of the adrenals or of the pituitary body causes the cessation of the genital functions with atrophy of the uterus. That there is some definite relationship between the ductless glands is, indeed, accepted by most workers, but what exactly these relations are is very debateable ground. There may be much truth in the deductions drawn by Dr. BLAIR BELL, who finds fault with BIEDL'S well-known work on this subject, because nowhere in it is there any attempt to link up the connexions that exist between the ductless

glands in regard to the specialised functions. In refraining from doing so, in our opinion, this distinguished writer is right; what we want is not hypotheses and speculation founded on our present imperfect knowledge, but a further laborious accumulation of facts and a very considerable increase in our understanding of this extremely complex and difficult problem.

Serum Diagnosis of Pregnancy.

The principle upon which Abderhalden's test is founded is the reaction of the blood to foreign substances introduced from without. The proteins contained in placental tissue thus produce a specific ferment and this can be detected in the blood serum of pregnant women from the seventh week of pregnancy up to 15 days after delivery. The test depends, of course, upon the presence of chorionic villi in the blood and tissues of the patient causing the production of a special ferment capable of bringing about their disintegration. The test is exciting at the present time a great deal of interest, and there seems no doubt that by its means it is possible to distinguish between the healthy pregnant and the healthy non-pregnant woman. It is true that the results so far obtained are far from uniform or entirely satisfactory, but this may well be explained by the fact that the method requires very great care in its use and an intimate knowledge of laboratory methods. The more carefully the elaborate technique which the author of this test has now evolved is followed the more certain and free from error are the results obtained, and in the hands of competent workers there seems no doubt that the test is accurate and of fair value. In a paper read by Dr. R. L. MACKENZIE WALLIS and Dr. HERBERT WILLIAMSON before the Section of Obstetrics and Gynæcology of the Royal Society of Medicine clinical details of 16 cases were given in which the test had been applied for purposes of diagnosis. The deductions drawn were correct in 12, incorrect in two, and still in doubt in the remaining two cases. Although it is hardly likely that this test will ever have much more than a theoretical value in the diagnosis of pregnancy, yet the work upon which it is founded is of the greatest possible importance because it seems to open up a large field of research in other diseases in which ferments are formed, and it also offers a possible method for obtaining further information on the subject of the so-called toxæmias of pregnancy. A similar test has recently been employed in the diagnosis of carcinoma, and in a paper in THE LANCET Mr. R. ST. LEGER BROCKMAN describes a series of 25 cases of carcinoma in which a positive result was obtained. Indeed, as he points out, some German observers claim that a differentiation between carcinoma and sarcoma can be made by this method.

The Contraction Ring.

Cases of dystocia from time to time occur in which some part of the uterus is contracted in a ring-like form either below or round a portion of the fœtus. A good deal of confusion has been introduced into the consideration of such cases by the failure of many writers to distinguish between two conditions which are probably of a different character. In an interesting paper read before the Section of Obstetrics and Gynæcology of the Royal Society of Medicine Dr. CLIFFORD WHITE distinguishes clearly between the retraction ring or the so-called ring of Bandl and the contraction ring. The latter may appear at any period during labour, it does not vary in position with the progress of the labour, and it is not necessarily associated with obstructed labour. It is, indeed, a local spasm of some of the circular fibres of the uterine muscle at varying level in different cases, and, as a rule, occurs round some part of the child, such as the neck or the knees, or in other cases it forms in front of the head and then may be regarded as an extreme degree of rigidity of the cervix. Dr. WHITE records three cases of this interesting condition, and his careful summary of their main features should do much to clear up the confusion which still exists upon the subject. Indeed, in a paper read by Professor R. JARDINE, subsequent to the appearance of Dr. WHITE'S paper, several cases of obstruction in labour due to the retraction ring are recorded which more probably were really cases of the occurrence of a contraction ring.

Hæmorrhage from the Placental Site.

The treatment of hæmorrhage from the placental site in the late months of pregnancy was an important question discussed at the Seventeenth International Congress of Medicine. The natural tendency for this subject to fall into two divisions (placenta prævia and accidental hæmorrhage) was accentuated by the decision of the reporters to choose one division each. It was perfectly clear, however, that the section was unanimous in dividing cases of hæmorrhage into two groups for purposes of treatment—viz., (1) those for whom the facilities of a hospital were available, and (2) those where these were impossible or refused. Almost every speaker urged this distinction, and many insisted that all cases of hæmorrhage were as clearly cases for treatment in hospitals or nursing homes as any acute surgical condition.

Professor DÖDERLEIN, in his discussion of placenta prævia, quoted the statistics of a very large number of cases. These included series treated by the following methods: (1) Artificial dilatation of the cervix by bags; (2) tamponade of the vagina; (3) Braxton Hicks's method of bipolar podalic version; (4) intra-amnial metreurysis; (5) abdominal Cæsarean section; and (6) vaginal Cæsarean section. He favoured operative measures (particularly vaginal Cæsarean section) where facilities were possible, but was still prepared to keep an open mind on the whole question.

Professor ESSEN-MÖLLER, who limited himself to the pathology and treatment of accidental hæmorrhage, referred to the recent discovery that, frequently at least, the muscle was the site of the hæmorrhage. He considered that a small group of cases was directly attributable to trauma, but that by far the larger group had an association with albuminuria such as to suggest the presence of some general intoxication. He drew comparisons between eclampsia and accidental hæmorhage, particularly in regard to the albuminuria and hæmorrhage. For treatment he advocated Cæsarean section (abdominal or vaginal) for serious cases with undilated cervix where the condition made rapid delivery necessary; hysterectomy was only to be done when uterine contractions remained obviously deficient after removal of the child and the placenta. He doubted the efficacy of the Rotunda method of plugging the vagina, and in moderate cases would try the effect of rupture of the membranes.

So far as the discussion related to placenta prævia there appeared more or less a consensus of

opinion that the Braxton Hicks method for most cases and Cæsarean section for severe cases with an undilated cervix gave the best prospects. Professor J. M. MUNRO KERR urged that the latter should not be postponed till late. Professor MURDOCH CAMERON was by no means enthusiastic over Cæsarean section, but Professor RECASENS was sufficiently convinced of its merit to have performed it when the child was dead. Professor R. JARDINE recommended pituitary extract for all cases of hæmorrhage, but Professor DE LEE pointed out that there was a danger of rupture of the uterus following this drug. Professor E. P. DAVIS regarded the condition as being essentially similar to ectopic gestation, and therefore treated it on surgical lines. He had had 14 cases treated by Cæsarean section with recovery of all the mothers and of all the viable children. Professor PAUL BAR and several others called attention to the possibility of an aggravation of the shock following cases of abdominal section.

Discussing accidental hæmorrhage, Sir JOHN BYERS remarked that, when concealed it gave rise to an appearance suggesting "something behind the bleeding." He thought that rupture of the membranes was bad if it delayed labour, and recommended the Rotunda method of packing the vagina, pituitary extract, and isotonic salines. Professor JARDINE described two cases of concealed hæmorrhage where the condition was too serious for Cæsarean section, and yet the patients recovered under pituitary extract, salines, and morphia; such cases pointed a moral. Dr. E. HASTINGS TWEEDY described thorough plugging of the vagina and its fornices as being invariably successful in arresting hæmorrhage by pressing on the large vessels; the patients, however, might still be in a dangerous condition even after the arrest of the hæmorrhage.

Radium and Roentgen Therapy in Gynæcology.

The most striking and interesting discussion at the Seventeenth International Congress of Medicine in the Section of Obstetrics and Gynæcology was that dealing with radium and Roentgen therapy in gynæcology. The extremely eulogistic terms in which some of the foreign speakers referred to the results obtained by these methods of treatment were listened to by a large and interested audience. The subject is one of the greatest possible interest and importance, and if the results claimed to be obtained turn out to be permanent and the method free from dangers it will produce little less than a revolution in, for instance, our methods of treating fibromyomata of the uterus and many cases of malignant disease. It must be remembered that some observers maintain that such unfavourable sequelæ as damage to the walls of the intestine and the formation of adhesions and even intestinal obstruction have occurred, and obviously as one of the speakers remarked, we must wait and see before accepting the results as proved. The first reporter was Dr. ALBERS-SCHÖNBERG, who communicated his results in a paper amplified by carefully tabulated statistics. His report included 46 cases of myomata, 26 of carcinomata, 35 of fibrosis uteri, a short series of menstrual abnormalities, and some cases of pruritus vulvæ; all of these were treated by X rays. Experiments had proved that the rays had a definite deleterious influence on the male and female genital glands. Their influence on myomata, however, was not solely due to ovarian atrophy, but included a direct action on the myomatous stroma. The great percentage of myomata did not disappear under treatment, but the percentage of complete relief from symptoms was a high one. Lasting cure was to be expected with certitude in favourable cases, but a certain number of myomata proved quite refractory; he did not consider that the indications for favourable cases were yet definite. He summed up the general indications for X rays in gynæcology as follows: (1) induction of menopause; (2) removal of post-climacteric bleeding; and (3) soothing of menstrual difficulties at all ages, *if possible* without sterilisation. He preferred to use as few rays as possible and to regulate by a varying exposure. Hæmorrhage might increase after the first or second dose, but later decreased.

The second reporter, Dr. FOVEAU DE COURMELLES, made it clear in his opening sentences that neither radium nor X rays must be regarded as a panacea. He had treated fibroids for the past ten years with X rays, and when applied discriminately was convinced of their great utility. Hæmorrhage and pain were usually the first to go, but young fibromata, even when of large size, yielded rapidly. The action was much more rapid about the menopause; failure occasionally occurred even after a preliminary improvement. Contraindications were: (1) polypi and (2) degenerating tumours. Discussing radium, Dr. DE COURMELLES found it possible to give a very favourable report in malignant disease. Of 100 cases of inoperable carcinoma 70 per cent. had improved for from 1–4 years, the mobility of the uterus had increased, hæmorrhage and leucorrhœa had diminished, and general improvement had rapidly appeared. He applied 1–5 cgr. of pure radium to the neck of the uterus for 6–24 hours. He hoped that bad as well as good results would be made public.

The Causes of Death among Infants during the First Four Weeks after Birth.

At the Seventeenth International Congress of Medicine an interesting debate took place upon this subject. Dr. A. K. CHALMERS, in opening the discussion, pointed out, firstly, that the deaths under one month formed almost one-third of the total deaths during the first year; secondly, that those occurring in the first week made up one-half of those occurring in the first month. It appeared that two-thirds of these deaths within a month could be ascribed to causes suggesting cell deterioration in the antenatal stage. He grouped such under the general term of "immaturity." Data appeared to suggest a strain of inefficient preparation for motherhood, or of inability on the part of one or other parent to beget healthy children, which was independent of surroundings and knew no geographical boundaries. Further tabulation of the causes of death in the days and weeks of the first month was urgently necessary for our further information. A sex variation, an age-period variation (under 20 and over 40), a relation to employment of the mothers and to social conditions in general, were clearly demonstrable. In conclusion, he was firmly convinced that nature and not nurture was at fault.

Dr. H. KOPLIK affirmed that the mortality under discussion was intimately connected with prenatal influences, and that the first month of extra-uterine existence was closely allied to the history of the fœtus in utero. Syphilis in statistics did not give a large quota of deaths, but this was probably due to difficulty of diagnosis. Obstetrical difficulties, the feeding of the infant, the legitimacy of the infant,

and the social position of the parents were all discussed. He considered that 60 per cent. of this deplorable mortality was due to neglect, ignorance, and poverty; prematurity alone would not account for a death, but prematurity and exposure would. Prematernity hospitals and instruction were a necessity; expert artificial feeding was preferable to wet nursing; and the education of the physician in obstetrics was not yet complete.

Professor V. WALLICH produced interesting statistics showing the variation between legitimate and illegitimate cases, and between home-nursed infants and those put out to nurse. The mortality from obstetrical reasons was improving, but much remained to be done in correcting detrimental social conditions.

In the discussion stress was laid by different speakers upon the great importance of prematernity supervision, the compulsory registration of still-births, the necessity for schools for prospective mothers, the immense importance of mothers nursing their babies, and the harm done by doctors and nurses in suggesting substitutes for breast-feeding.

OPHTHALMOLOGY.

Recent advances in ophthalmology may best be judged from the proceedings of the Section of Ophthalmology of the Seventeenth International Congress of Medicine. The noteworthy work of the past year in the various branches of the subject, both clinical and experimental, found its appropriate exponent and suitable presentation at the meetings held in London. The section was unfortunate in losing its President-Elect by death. Sir HENRY SWANZY was well known not only to ophthalmologists but to most students of medicine as the author of a very popular manual on diseases of the eye. As an ophthalmic surgeon of outstanding merit his loss was deeply deplored. Amongst the active members of the Congress was another ophthalmic surgeon whose death we have since had to record. Mr. EDWARD NETTLESHIP could ill be spared; full as ever of enthusiasm, with his mental capacities undulled by age, he piled up day by day the debt we owe him. At a time when he had fully earned repose he was still pursuing his researches with all the vigour of youth. Some of the material he had gathered still remains unpublished, but the moving finger is stayed.

Discussions at the International Congress of Medicine.

The formal discussions at the Congress were devoted to the subjects most prominently in the minds of ophthalmic surgeons of the day. They included all types of chronic uveitis other than syphilitic, tuberculous, and sympathetic; the operations for glaucoma, with special reference to the comparative results of iridectomy and its modern substitutes; diseases of the eye caused by undue exposure to light; and the rôle of anaphylaxis in ophthalmology. The reporters were chosen from those who had given special attention to the respective subjects, and many found the occasion opportune to add the records of further researches. No better equipped authorities on the difficult problem—chronic uveitis—could have been selected than Professor E. FUCHS and Dr. DE SCHWEINITZ. The former gave a masterly survey of the pathological anatomy of the disease and its bearing upon the vexed question of pathogenesis. Dr. DE SCHWEINITZ dealt with the clinical features and supplemented these observations with biochemical and other investigations. The view that the disease is due to auto-intoxication or actual bacterial metastasis from some septic focus in the body received much support, and if the last word has by no means been said, the lines of future research have been indicated.

Professor PRIESTLEY SMITH was naturally chosen to open the debate on glaucoma. His profound knowledge of the disease, his wide experience of the older operations, especially iridectomy, and his admirably balanced judgment, all combined to produce a critical estimation of iridectomy, corneal trephining, Lagrange's and Herbert's operations, and other procedures which could scarcely be bettered. The contributions of Lieutenant-Colonel R. H. ELLIOT, Professor LAGRANGE, and Lieutenant-Colonel H. HERBERT aroused the greatest interest, and the discussion on this very important subject must be regarded as the most successful of those held in this section. Professor C. VON HESS and Mr. J. HERBERT PARSONS were the reporters on the effects of bright light. They reviewed the diseases due to this cause, such as eclipse blindness, ophthalmia nivalis and electrica, glassworkers' cataract, &c., and discussed the causes, pathological anatomy, and means of protection. Attention was drawn to the milder disabilities which may result from exposure to light, a subject which has attained such practical importance as to lead to an inquiry by a Departmental Committee of the Board of Trade, with special reference to the lighting of factories. Mr. RICHARDSON CROSS emphasised the importance of collecting evidence of disease due to such exposure to ordinary illuminations, and it is hoped that the discussion will stimulate response in this direction.

Anaphylaxis is a subject to which most ophthalmologists had probably paid little attention, but Professor MORAX and Dr. A. SZILY gave ample reason for a better acquaintance with it. The latter's communication was a monograph of over 200 pages, which should be studied by every ophthalmologist, and will be found well worth consideration by others interested in the matter. It is well known that Professor ELSCHNIG has invoked anaphylaxis to account for sympathetic ophthalmia, and though few have been found to accept his views they cannot be wholly disregarded. More striking are WESSELY'S researches on the cornea. It has long been a mystery why in interstitial keratitis the second eye almost invariably becomes affected after an interval of some weeks, irrespective of treatment. Moreover, interstitial keratitis is known to follow slight injury in certain subjects, and though the causal relationship has been doubted the evidence is considerable. WESSELY'S experiments offer a plausible explanation of these facts, and whether the explanation be true or not the experiments themselves are so striking as to merit careful attention. If a few drops of horse serum are injected into the parenchyma of the cornea of a rabbit the latter rapidly regains its normal appearance. If, however, after an interval of a fortnight a second injection of the serum is made *intravenously* the injected cornea rapidly becomes vascularised and in all respects resembles an ordinary case of interstitial keratitis, whilst the other cornea remains normal. These facts must have some deep significance and point the way to further research.

Intracapsular Extraction of Cataract, &c.

One subject which has attracted much notice in recent years—intracapsular extraction of cataract—was conspicuous by its absence from the proceedings of the Congress. An able exponent of Colonel SMITH'S method, Dr. GREEN, has died very recently. The impression we have gained of the status of the operation in India is that the severe and almost universal condemnation which it met with at first has had to be modified. It appears to have made a place for itself in a small group of selected cases, but is still generally condemned as a routine method. Whatever may be the case in India, in most other parts of the world ophthalmologists are generally agreed that it is fraught with danger.

During the past year the Ophthalmological Society has held its first meeting under the new *régime* as an annual "congress." The meeting was very successful in spite of its proximity to the International Congress, and will doubtless be still more so in future years.

The newly founded Section of Ophthalmology of the Royal Society of Medicine has also had a most successful session. The amity which reigns between the two societies is agreeably displayed in the presentation of the library of the Ophthalmological Society to the Royal Society of Medicine and the reciprocal facilities which have been given to members of the former society by the latter.

NEUROLOGY.

Syphilis, Parasyphilis, and General Paralysis.

It has become increasingly apparent that the term parasyphilis is misleading and out of date—i.e., in so far as it has been supposed to signify a diseased state, not actually syphilitic, but a sequel to preceding syphilis. The evidence of the year now drawing to a close has shown that patients suffering from general paralysis are actively syphilitic. NOGUCHI and MOORE[1] demonstrated the treponema pallidum by a modification of Levaditi's silver method in 12 out of 70 brains of patients dying with general paralysis. In a second series examined by NOGUCHI,[2] he has found the spirochæta in 36 out of 130 cases. His results have received sufficient confirmation in the course of the last few months, although it appears that with the method of smears with Indian ink and a dark background the spirochæta can be seen more readily than by silver methods. MARIE, LEVADITI, and BAUCHOWSKI[3] have reported the constant presence of spirochætæ in the brains of general paralytics dying in seizures. They report that they have recovered the organism still motile from the frontal cortex in general paralysis. MOTT[4] has published his results with various methods of examination—Levaditi method, Indian-ink method, Fontana-Tribondeau silver method, the last of which he thinks is the most satisfactory. He has recovered spirochætæ still moving, though sluggishly, from the cortex of general paralysis no less than four days after death. By the Indian-ink method he has found the organism in 8 out of 11 cases. The spirochætæ are not found in relation to cerebral or cortical blood-vessels, but are free in the tissues, and may have to be searched for with exemplary patience. MARINESCO and MINEA[5] have shown that they may occur in nests, so to speak.

Further, GRAVES[6] has experimented along the lines of inoculation of rabbits' testicles with the blood of cases of general paralysis and tabes dorsalis. Two positive results were obtained. Distinct areas of induration developed, in which typical spirochætæ were found. NOGUCHI[7] has inoculated the testicles of 36 rabbits with fresh emulsion of the brain in general paralysis. In two instances after an interval of about 100 days typical induration of the testicle developed, and in this affected area spirochætæ were discovered, in one case in abundance.

Such experimental work is of the utmost significance. It is now demonstrated that syphilis can be produced in rabbits from the emulsified cortex of general paralysis. Many problems remain, one of the most important being the question of the occurrence of a granular stage of the spirochæta pallida.

A new method of treatment of tabes dorsalis and general paralysis is suggested by a consideration of the way in which the spirochæta is disseminated through the tissues in these diseases. SWIFT,[8] of the Rockefeller Institute, has been treating such cases by preliminary intravenous injection of salvarsan. One hour later the blood of the same patient is taken, centrifuged, the serum diluted with normal saline, and after withdrawal of a corresponding quantity of cerebro-spinal fluid injected into the subdural space by lumbar puncture. He claims to have obtained good results thereby. FISHER[9] has utilised approximately similar methods, and has obtained great improvement, with arrest of symptoms, in seven cases of advanced general paralysis.

Progressive Lenticular Degeneration and Pseudo-sclerosis.

Great interest has been taken, especially in Germany, in the disease described by KINNIER WILSON as "progressive lenticular degeneration," a disease in which bilateral lesions of the corpus striatum, in particular the lenticular nucleus, are associated with cirrhosis of the liver. During the year since the publication of his monograph cases have been recorded by CASSIRER,[10] SAWYER,[11] STÖCKER,[12] YOKOYAMA and FISCHER,[13] and SCHÜTTE.[14] In these cases the symptomatology has been identical with, or very similar to, that already described as characteristic of bilateral disease of the corpus striatum—viz., involuntary movements, usually tremors, spasticity of the limbs, leading to contractures, helplessness without actual paralysis, involuntary laughing, with no signs of involvement of the pyramidal tracts. Recently, also, fresh cases of so-called pseudo-sclerosis of a special type have been reported by WESTPHAL,[15] HOESSLIN and ALZHEIMER,[16] and RUMPEL.[17] These have been cases in which cirrhosis of the liver has been found at

necropsy, and in which the clinical symptoms have been somewhat analogous to those referred to above, but gross changes in the corpus striatum have not been discovered. The whole subject gave rise to a fruitful discussion at the recent Jahresversammlung[18] der Gesellschaft Deutscher Nervenärzte in Breslau. It is clear that in Wilson's type and in this variety of so-called pseudo-sclerosis we are dealing with a condition the investigation of which has thrown much needed light on the question of the functions of the corpus striatum, as well as on the familiar disease paralysis agitans.

The Sensory System.

TROTTER and DAVIES,[19] of University College Hospital, have published an important communication embodying researches that have extended over six years. By experimentation on themselves they have re-examined the evidence adduced by HEAD some years ago to show that the peripheral sensory system (cutaneous part) was divisible physiologically into protopathic and epicritic systems, a view which had much to commend it and which has been to a large extent accepted. TROTTER and DAVIES cannot confirm the criteria of distinction between the two systems which HEAD described, and they believe that the phenomena of regenerating sensibility are capable of a simpler interpretation than that given by the latter observer.

Poliomyelitis.

A few minor epidemics of this disease have been reported in England this year by ROTH[20] and by JUBB.[21] MCINTOSH and TURNBULL[22] have successfully inoculated monkeys with emulsions of spinal cord obtained from four cases of poliomyelitis occurring in the London Hospital district. They have found it difficult to transmit the virus from sporadic cases; in epidemics transmission is successful in the great majority of cases. They suggest that epidemics take place only when the potency of the virus has become aggravated from circumstances as as yet unknown. FLEXNER and NOGUCHI[23] have apparently been successful in distinguishing and cultivating the virus of the disease. They have isolated from the central nervous system of poliomyelitic patients and of infected monkeys a minute micro-organism consisting of globoid bodies whose dimensions vary from 0·15 μ to 0·3 μ in diameter, arranged in pairs, chains, or masses. They grow in human ascitic fluid and can pass Berkefeld filters. Further, these organisms are capable of reproducing the disease in monkeys, and from these, again, it can be recovered in pure culture. The organism is anaerobic.

Pellagra.

Pellagra in a more or less classical form has made its appearance in Great Britain during the past year, although the probability is that previous cases of the affection have to a large extent escaped recognition. It is most likely to be detected by the skin lesions, or to come first to the notice of the dermatologist. SAMBON[24] has drawn attention to the occurrence of the disease, and cases have been reported by BOX,[25] BLANDY,[26] JOHNSTON,[27] REID and CALWELL,[28] HAMMOND,[29] COLE,[30] and others. MOTT[31] has reported on the pathology of one of the English cases. A number of the published cases have occurred in asylums. They have been characterised by a symmetrical dermatitis of the backs of the hands and forearms, sometimes spreading round to the radial side of the palmar aspect, but respecting as a rule the terminal phalanges, similar dermatitis on either side of the neck and on the face, stomatitis, gastro-intestinal symptoms, and the usual, though varying, nervous symptoms of paræsthesiæ, pains, weakness of the extremities, ataxic paraplegia, and a spastic-ataxic gait. It is important that the practitioner should be on the alert in this matter; the disease shows well-recognised seasonal variations, and it may be expected that next spring more cases will be forthcoming. At present the evidence is strongly against the hypothesis that corn products alone are the causative agents of the disease (SILER and GARRISON).[32] The view of SAMBON that the disease is associated with the presence of the simulium fly has been combated by ROBERTS.[33]

Ductless Glands.

This subject continues to attract an immense amount of clinical, pathological, and experimental investigation, to which only the scantiest reference is here possible, while it also receives attention in another column in relation to the pelvic organs.

SWEET and ALLEN[34] have performed complete hypophysectomy on 22 adult dogs. On necropsy the following changes were constantly found: (1) a striking red colouration of the pancreas, without much microscopical alteration; (2) testicular atrophy; (3) increase of body weight and obesity. They believe the entire hypophysis can be removed without danger to life. WEED, CUSHING, and JACOBSON[35] have shown that in cats, rabbits, and dogs the posterior lobe of the pituitary body plays a significant rôle in the metabolism of carbohydrates, and its action in this respect is under the control of fibres coming from the superior cervical sympathetic ganglion. DANA and BERKELEY[36] have published an extremely interesting paper on Pineal Feeding Experiments in Young Animals and in Children. Extracts of the pineal gland of young bullocks were utilised. Their use was followed in animals by increase of body growth and of metabolic activity. "Fifty cases of backward children, under the age of eight or nine years, when fed on pineal extracts, gave results which astonished and pleased their school teachers." DEGENER[37] removed the thyroid glands *in toto* from 12 adult rabbits, and found that the hypophyses were always heavier than in control animals. After some six months had elapsed between the date of experimentation and the death of the animal, the pituitary was found to have increased to about three times its normal size. CLAUDE, BAUDOUIN, and PORAK[38] failed to obtain glycosuria after injection of posterior pituitary lobe extract in 12 young subjects

who were definitely phthisical. Similarly, they could not produce it in rabbits after experimental tuberculisation.

ELECTROTHERAPEUTICS AND RADIOLOGY.

A very significant feature in the field of modern electrotherapeutics is the gradual supersession of the time-honoured galvanism and faradism by the discharges from condensers for treatment as well as for diagnosis. Condenser discharges have practically revolutionised electro-diagnosis; instead of the rather crude results formerly obtained, it is now possible to differentiate many degrees of muscle degeneration, and the progress of a case can be determined with an accuracy that is all but complete. It would be difficult to over-estimate the importance of this development, especially in these days of increasing malingering. So also in the treatment of neuron and muscle lesions. The tendency at the present time is to use strong currents and long applications, but with the ordinary induction coil currents there is a certain amount of movement of ions that gives rise to discomfort and pain. With condenser discharges the impulses are so short that little sensory effect follows. The same may be used in the treatment of obesity with the result that we get a maximum of muscular contraction with a minimum of sensory effect. This method of dealing with corpulence was introduced by BÉRGONIÉ and seems to be both safe and efficient.

High-frequency currents are gradually finding a place in the reduction of hypertension, and a series of applications seems to establish some degree of permanence. The value of the low-tension variety known as diathermy is still under consideration and investigation. It possesses the unique property of heating the tissues through which it passes, even to the extent of coagulation if desired, and a wide field of usefulness is probable as its action becomes better understood.

Radiology in Diagnosis.

The science of radiology continues to make rapid progress. As regards diagnosis, what with increasing skill, greater experience, and better appliances, accuracy of a very high order is being attained in many directions. In the detection of incipient phthisis it holds a very strong position. A clinical diagnosis is frequently anticipated, and when used for corroboration it shows an extent of invasion beyond that detected by clinical methods. In the diagnosis of urinary stone almost complete accuracy is attained; gall-stones are relatively transparent to the X rays, but their detection by this method is becoming more frequent. The investigation of diseases of the digestive system by the X rays has advanced so rapidly during the last year or two that it has been difficult to keep pace with it. An enormous amount of the most valuable information regarding the whole digestive tract has been gained by this method, and it is being added to every day. Nowadays no investigation of the digestive organs is complete without watching the progress of a meal that has been charged with bismuth of barium to make it opaque, and the skill that has been attained in the interpretation of these shadows is highly creditable to those who have done so much to advance this line of investigation. The study of renal disease is also much helped by the injection of an inert opaque solution of collargol into the pelvis of the kidney, which is then examined by the X rays. Certain conditions of the pelvis of the kidney, for instance, are shown up with great clearness, and as the catheter is purposely made opaque to the rays, the course of the ureter is accurately shown.

Nothing new in the way of apparatus, beyond improvement in details, has been brought forward. At present the greatest need is for a tube or other device, capable of furnishing the large volume of radiation required to meet modern demands, and to be capable of doing this steadily for comparatively long periods of time. In the light of present-day requirements the X ray tube itself is the weak member of the radiologic outfit; it is just possible we have about reached the limit of its development along existing lines, and the X ray generator of the future may be something quite different to our present ideas.

Therapeutic Use of X Rays.

The use of the X rays for therapeutic purposes has made steady progress, one of the most important recent developments being the treatment of uterine fibroma. Though the facts may not completely justify the enthusiasm of those who so strongly advocate this method, yet the results that have been obtained, especially on the continent, are sufficiently remarkable to demand our serious attention. The uterus is attacked by large doses of very hard rays, directed from various points on a "cross-fire" principle; the skin does not suffer, and the relief of symptoms and reduction in size of the tumour have been very marked. The method is practically certain of a recognised place in the treatment of this disorder. Another recent application of the X rays is that of the reduction of hypertension, where this is due to an excessive activity of the suprarenal glands. Definite changes in the structure of these organs are produced by irradiation, and their secretion diminished. Favourable results have been obtained in a good proportion of cases, and the idea seems to be one that is worth following up.

The great value of the X rays in dermatology and superficial conditions generally has received further support during the year.

DERMATOLOGY AND SYPHILOGRAPHY.

Salvarsan.

The most important event during the year was the address given by Professor EHRLICH at the International Medical Congress on the Treatment of Syphilis by Salvarsan and Allied Substances. He dealt mainly with the chemical aspect of the subject. He mentioned that some observers had denied that salvarsan had any action on the spirochætæ, but it was certain that if salvarsan and some spirochætæ be mixed together in a test-tube and the mixture injected, then no syphilis would result, because the spirochætæ had been "anchored," or fixed, so that they were more easily attacked by the fluids and tissues of the body. He claimed that with salvarsan there was little toxic effect of the nervous system. In a very few cases there might perhaps be a special idiosyncrasy to salvarsan, but it must be of extreme rarity, and some of the fatal results were certainly due to errors of technique, but at all events the percentage of fatal cases from salvarsan was very small. It was of the greatest importance to abort syphilis in the earliest stage, though even in the later stages very good results might be obtained.

In the discussion which followed the valuable work that has been carried out by the Royal

Army Medical Corps in the use of salvarsan was deservedly praised. The conclusions at which Lieutenant-Colonel T. W. GIBBARD and Major L. W. HARRISON, who contributed the paper, had arrived were that the best results were obtained by the administration of three intravenous injections of 0·6 grm. salvarsan and ten intramuscular injections of mercury spread over nine or ten weeks, and the earlier in the primary stage the treatment was commenced the less the chance of a relapse. In the British army more than 70,000 days of hospital treatment had been saved, leading to a great economy of money. As to the risk of the treatment, they had given over 3000 injections and had had no fatality. Professor A. NEISSER also made a valuable contribution to the debate. He insisted on the importance of trying to "sterilise" the patient in the early stage, for then it can be done most easily, and on the desirability of applying the Wassermann test to the cerebro-spinal fluid as well as to the serum. The communication from Sir MALCOLM MORRIS and Dr. H. MACCORMAC was based on a series of 500 injections; when the treatment had been commenced during the primary stage they had invariably prevented the appearance of secondary symptoms. Many others also spoke, and there was on the whole a great degree of unanimity between the speakers. It was generally agreed that two or three doses of salvarsan were needed, and that they should be followed by a course of mercury.

Royal Commission on Venereal Disease.

The appointment of a Royal Commission on the Prevalence and Effects of Venereal Disease should prove of value in drawing attention to the extent and importance of this scourge and in devising some methods of controlling it. The Commission was appointed mainly as a response to an influential memorial signed by many eminent persons, and the wide terms of the reference show that the Government was fully alive to the importance of the subject. The reference to the Commission was: "To inquire into the prevalence of venereal diseases in the United Kingdom, their effects on the health of the community, and the means by which those effects can be alleviated or prevented, it being understood that no return to the policy or provisions of the Contagious Diseases Acts of 1864, 1866, or 1869 is to be regarded as falling within the scope of the inquiry." The *personnel* of the Commission has met with general approval, though it might have been well to include in it a member of the Royal Army Medical Corps and a naval surgeon. It is to be hoped that the work of the Commission will proceed as rapidly as is possible with a due regard to the thoroughness of its work, that the report may be issued without delay, and that the Government will take action on the report as soon as the legal requirements can be fulfilled.

Vaccine Treatment of Skin Diseases.

A subject of great importance was discussed at one of the meetings of the Dermatological Section of the Congress—namely, the Vaccine Treatment of Diseases of the Skin. As Professor GILCHRIST, of Baltimore, said in his opening paper, the too promiscuous employment of vaccines, especially of the commercial forms, has done much to discredit the use of these remedies. Even in the most skilled hands there are many failures. Vaccines appear to be of the most use in acute and chronic staphylococcic lesions of the skin, and autogenous vaccines are best, but in certain cases stock vaccines have proved useful. In this opinion most of the other speakers agreed. Professor ARTHUR WHITFIELD expressed his appreciation of the value of the opsonic index, not so much as a clinical guide as to the dose of a vaccine or for the time of its administration, but rather as enabling the physician to decide which out of a number of organisms, obtained by culture, was responsible for the lesion present. Very good results could be achieved in acute infections, such as erysipelas. In some conditions, such as acne vulgaris, very large doses were sometimes needed, and he gave from 125 to 250 millions of the micro-bacillus. Other speakers also pointed out that it was only in certain forms of infection of the skin that vaccine therapy could produce good results. It was clear from this discussion that the vaccine treatment of diseases of the skin is still in an unsettled position, although some very definite results have been obtained with a few forms of infection.

Epithelioma of the Skin.—Alopecia.

Another discussion of no little importance was that held on the subject of Epithelioma of the Skin, Innocent and Malignant. It was opened by Dr. J. DARIER, and he was followed by a large number of speakers, and it must be confessed that as a result of the whole discussion it was felt by many that there was much still to be learned as to the true nature of these epithelial growths.

The difficult question of the Nature and Treatment of Alopecia Areata and Allied Conditions also engaged the attention of the Congress. So great an authority as Dr. SABOURAUD declared that alopecia areata was a non-microbic and non-contagious malady, and this view was accepted by the majority of those who took part in the discussion, though Dr. J. H. SEQUEIRA believed that there might be a few which were of a contagious nature, and Professor JADASSOHN was of the same opinion. So the question of the contagiousness of the disease cannot as yet be regarded as settled. The probable explanation of the divergence of views is to be found in the multiplicity of the nature of the cases described under the title of alopecia areata.

Pellagra.—Leprosy.—Finsen Light Treatment.

Of recent years the spread of the disease called pellagra has attracted much attention, for it has invaded countries where it was unknown before; it has invaded the United States of America, and it has now been described also in this country. Though in its later stages it is of the most importance as affecting the nervous system, yet at first it appears mainly an affection of the skin, and it is as a skin disease that it is first likely to be recognised. There can be little doubt that many cases of the disease do exist in this country and that a correct diagnosis is rarely made.

The early diagnosis of leprosy is often by no means easy, and therefore it will be of value to note the method employed by Dr. THOMAS MILLER of Manitoba, in a doubtful case. He was able to show by means of a skiagram that the phalanges of one great toe had been in part destroyed; it was said that the toe had been decreasing in size for the last two years, and this with other symptoms suggested leprosy, but the existence of the destruction of the bones as shown by the X rays made the diagnosis certain. A valuable contribution to the Study of the Finsen Light Treatment in England has been furnished by a report from Dr. J. H. SEQUEIRA on the use of the treatment at the London Hospital

from 1900 to the present year; and in this report it is shown that in a very large proportion of the cases a permanent cure of the lupus has been effected, while in others much improvement has occurred. Only in a very few cases has no benefit resulted.

TROPICAL AND EXOTIC DISEASES.

Tropical medicine still continues its triumphal march with the result that 1913 has seen much real progress in our knowledge of the origin, treatment, and prevention of the diseases most frequently met with in the tropics. It is a matter of congratulation that the London School of Tropical Medicine has already obtained nearly three-fourths of the sum of £100,000 required to place its operations on a better and more substantial basis. The great event of the year was the Seventeenth International Congress of Medicine in London, this being the first occasion on which a section has been devoted exclusively to the subject of tropical medicine and hygiene. The success of this section, which had for its president Surgeon-General Sir DAVID BRUCE, must have gratified its organisers. It more than justified its existence, for its meetings were thronged at every sitting by members from all parts of the world, some of whom were among the "giants of tropical medicine"; and these distinguished men, by taking part in the discussions, lent additional weight and dignity to the proceedings. Many valuable and interesting papers were read at the meetings of the Section of Tropical Medicine, but we direct special attention to a series of discussions which were arranged by the officials for particular consideration by the members, the subjects being plague, beri-beri, leishmaniasis, spirochætosis, and sanitary organisation in the tropics.

Discussions at the Seventeenth International Congress of Medicine.

The *discussion on plague* was opened by a paper prepared by Professor S. KITASATO (Japan), who testified to the value of the guinea-pig in the search for plague-infected rat-fleas in human habitations. Major W. GLEN LISTON spoke on the epidemiological features of bubonic and pneumonic plague, and on the immunity of Mus rattus to plague infection. A very interesting demonstration, with the aid of lantern slides, was given by Dr. C. J. MARTIN and Mr. A. W. BACOT, of the Lister Institute, on the mechanism of the transmission of plague infection by rat-fleas. The relationship of the tarbagan to human plague was dealt with by Dr. WU LIEN TEH (G. L. TUCK), director of Plague Preventive Measures in Northern Manchuria (whose paper was published in full in THE LANCET of August 23rd). Among others who took part in the discussion were Dr. R. ROW (Bombay), Dr. F. J. VAN LOGHEM (formerly of Java), Mr. J. CANTLIE (London), Dr. A. AGRAMONTE (Cuba), and Dr. DUNCAN WHYTE (China).

The discussion on beri-beri.—The importance attached to this may be estimated by the number of eminent men who took part in the debate. Dr. C. EIJKMANN (Utrecht), whose name has long been before the scientific world as an investigator of beri-beri, opened the discussion, and was followed by Dr. B. NOCHT of Hamburg. Dr. L. BRADDON (Federated Malay States), who was one of the very first to press the "white rice" theory of the causation of the disease, and Dr. C. FUNK (of the Lister Institute), who described the neuritis-preventing "vitamine" found in the subpericarpal layers of the rice grain, set out their views fully; and those who also spoke included Dr. H. SCHAUMANN (Hamburg), Dr. S. SHIBAYAMA (Tokio), Professor F. RHO (Rome), Dr. T. SHIMAZONO (Tokio), Dr. L. NATTAN-LARRIER (Paris), Dr. MALCOLM WATSON (British Malaya), Dr. J. TSCHUDNOWSKY (Paris), Dr. G. L. FINK (Burma), Dr. D. E. ANDERSON (London), Dr. AGRAMONTE, Dr. L. SAMBON (London), Miss MAY YATES (London), Mr. CANTLIE, Dr. E. DE FREITAS CRISSIUMA (Brazil), Dr. L. G. CHACIN-YTRIAGO (Venezuela), Dr. C. NOEL DAVIS (Shanghai), and Sir PATRICK MANSON. The section passed a series of resolutions respecting the etiology and prevention of the disease, embodying the views now generally held as to the danger of white rice as a staple article of diet.

The discussion on leishmaniasis was opened by Professor A. LAVERAN (Paris), who read a paper prepared by himself and Dr. C. NICOLLE (Tunis) on Infantile Kala-azar. Sir WILLIAM B. LEISHMAN set out briefly the state of our present knowledge of the leishmania infection and its various forms. Others who took part in the debate were Dr. ROW, Dr. NATTAN-LARRIER, Dr. CRISSIUMA, Dr. B. GONDER (Frankfort-am-Main), Dr. AYRES KOPKE (Lisbon), Dr. A. SPLENDORE (Brazil), Professor RHO, Dr. ANDERSON, Dr. L. P. PHILLIPS (Cairo), and last but not least, Sir PATRICK MANSON.

The discussion on spirochætosis.—This was opened by Professor S. HATA (Tokio) with a contribution to our knowledge of the cultivation of the spirochæta recurrentis; he was followed by Dr. E. PRIMET (French Equatorial Africa), Dr. ANDREW BALFOUR (formerly of Khartoum), and Dr. S. T. DARLING (Panama Canal Zone). Sir WILLIAM LEISHMAN wound up the debate by discussing the question of granule shedding in spirochætosis, and showed some instructive lantern slides in support of his views.

The discussion on sanitary organisation in the tropics.—This was discussed at a joint meeting of the Section of Tropical Medicine and Hygiene and that of Naval and Military Medicine. The debate was opened by Sir RONALD ROSS, who was followed by Staff-Surgeon Dr. HINTZE (of the German Colonial Medical Service), and among others who took part in this interesting discussion may be mentioned Colonel P. HEHIR, I.M.S., Colonel W. G. KING, I.M.S. (retired), Professor T. v. WASIELEWSKI (Heidelberg), Dr. AGRAMONTE, Dr. C. BLACK (Western Australia), Dr. F. M. SANDWITH (London), Dr. C. F. HARFORD (Leyton), Dr. G. OLPP (German West Africa), Dr. ANDERSON, Dr. ANDREW BALFOUR (London), Dr. KOPKE, Dr. WATSON, Colonel BRUCE SKINNER, R.A.M.C. (London), Major LISTON, I.M.S., and Sir PARDEY LUKIS (Director-General, I.M.S.).

Presentation to Sir Patrick Manson.—At one of the closing meetings of the Section of Tropical Medicine of the Seventeenth International Congress of Medicine Professor BLANCHARD, of Paris, in the name of the International Society of Tropical Medicine, presented, with the accompaniment of a graceful and sympathetic speech, to Sir PATRICK MANSON ("the father of tropical medicine") a handsome medallion designed specially by Professor RICHER, of the Paris School of Fine Arts, having on one side of it a likeness of the recipient. The presentation was made amid the enthusiastic plaudits of the members, but the heartiness of his reception caused Sir PATRICK some emotion, and it was with difficulty that he was able to return his thanks.

The Spread of Disease in Africa by Wild Animals and Insects.

The Secretary of State for the Colonies in August, 1913, appointed a committee to report upon the present knowledge available as to the parts played by wild animals and tsetse flies in Africa in the maintenance and spread of trypanosome infections of man and stock; whether it is feasible to carry out an experiment with regard to game destruction in a localised area; whether it is advisable to attempt the extermination of wild animals locally or generally with a view of checking trypanosome diseases; and whether any other measures should be taken to obtain means for controlling these infections. The medical members of this committee comprise Dr. A. G. BAGSHAWE, Dr. ANDREW BALFOUR, Sir JOHN ROSE BRADFORD, Dr. W. A. CHAPPLE, M.P., Sir WILLIAM LEISHMAN, and Dr. C. J. MARTIN. Professor R. NEWSTEAD and Dr. P. CHALMERS MITCHELL are also members of the committee, of which the Earl of DESART is the chairman. It may be remembered that this subject was also raised in the final report of the Luangwa Sleeping Sickness Commission by Dr. ALLEN KINGHORN and Dr. WARRINGTON YORKE.

Inquiry into the Nature and Frequency of West African Coast Fevers.

The Colonial Office, in view of the conflicting opinions expressed respecting the fevers occurring on the West Coast of Africa, appointed in 1913 a small Commission of experts to study the nature and relative frequency of such fevers, and especially as regards yellow fever and its possible minor manifestations among natives and others in West Africa; and to study the clinical course, pathology, and mode of infection of such fevers and the diseases for which they may be mistaken; the nature of bilious remittent, malignant bilious remittent, "inflammatory," endemial and "acclimatising," and other forms of fever was to be investigated under the direction of this Commission, the members of which are Sir JAMES KINGSTON FOWLER (chairman), Sir RONALD ROSS, Sir WILLIAM LEISHMAN, and Professor W. J. R. SIMPSON.

Special Investigations of Diseases in India.

Special investigations are now in progress in India respecting the etiology, treatment, and prevention of a number of diseases, including kala-azar, plague, cholera, relapsing fever, and dysentery, the cost of which is defrayed, in whole or in part, by the Indian Research Fund Association, which was founded in 1911. In this connexion we may refer to an article published in *Science Progress* by Sir PARDEY LUKIS, which shows how at present the practical application of scientific investigations is now being made use of in India with resulting great improvement in the sanitary circumstances of the Indian people, accompanied by welcome developments in local sanitary administration. The Central Research Institute is located at Kasauli under the charge of Major S. R. CHRISTOPHERS, I.M.S. The Third All-India Sanitary Conference has not been held during 1913, but takes place in January, 1914.

Pellagra.

Pellagra, though not, strictly speaking, a tropical disease, is regarded by most people as an exotic, though lately Dr. L. SAMBON and others have reported some 40 cases in England, Scotland, and Wales, while Dr. F. E. RAINSFORD sent to the columns of THE LANCET the notes of a case occurring in Ireland. The investigations of the Pellagra Commission are being continued, and in this connexion Dr. SAMBON has recently visited the United States of America, where it is estimated some 30,000 persons are at present suffering from the disease. The malady is reported to be prevalent, among other places, at Porto Rico, the Panama Canal Zone, the Philippines, and the Sandwich Islands. The difference of opinion as to whether this disease is due to a specific infection or a toxin, or is due to a deficiency of some essential substance in the diet, has not yet been settled, though researches by Dr. SAMBON and other experts are in progress, as well as investigations by an American Commission. A recent report by Dr. HUGH S. STANNUS shows that pellagra is endemic in Nyasaland.

According to our custom we give a short summary of the reported occurrences of the three exotic diseases, cholera, plague, and yellow fever, as well as of small-pox in various parts of the world during 1913 so far, at least, as the information has been obtainable.

Cholera in India and the Far East.

Cholera was prevalent in various provinces of India, and so far as can be gathered from the limited amount of information available up to date, about 150,000 deaths were registered from the disease during the first nine months of the year. The worst sufferers were Bengal, the United Provinces of Agra and Oudh, the Madras Presidency, the Central Provinces, and the new province of Bihar and Orissa. The disease was continuously present during the year in Calcutta, where about 1200 deaths were recorded up to September. In Bombay City cholera caused about 125 deaths in the same period. The malady appeared during 1913 at the Burmese ports of Rangoon, Bassein, and Moulmein, and at Madras and Negapatam in the Madras Presidency. In Ceylon 30 fatal cases occurred at Colombo; and in the Straits Settlements at Singapore about 200 cases were reported. The disease was reported to have occurred on the west coast of the Malay Peninsula, and about 70 fatal cases were certified in Bangkok, the capital of Siam. Cholera was prevalent in Indo-China, outbreaks being reported in Annam, Cambodge, Cochin China, Laos, and Tonkin. The Dutch East Indies suffered again from cholera in 1913, the islands of Java, Sumatra, Borneo, and Celebes being affected. In the Philippine Islands the malady appeared in August at Manila, causing over 70 deaths up to November. In China cholera was present in Amoy, Swatow, Canton, Hong-Kong, Foochow, Chuan-Chow, and elsewhere. Several prefectures in Japan were invaded by cholera during the year, and cases were notified at the ports of Kobe, Nagasaki, and Yokohama, as well as in the island of Formosa.

Cholera in the Near East.

Cholera was epidemic in Asia Minor and the Hedjaz up to the end of 1912, and in the early part of 1913 a few cases were heard of in these regions, the disease then seeming to disappear altogether. It was not until July that cholera once more broke out in Asia Minor at Smyrna, where up to September about 300 persons had been attacked. The malady also reappeared in August in the Red Sea provinces of Turkey at the port of Hodeidah in Yemen, where some 123 cases were notified up to September, chiefly among the Turkish troops.

Cholera in Europe.

Cholera was acutely epidemic at the end of 1912 in Constantinople and in its vicinity, especially at Tchatalja, where the Turks made their final stand to arrest the advance of the then victorious Bulgarians. In the early part of 1913 news came from Bulgaria and Macedonia that cholera had been introduced by Turkish prisoners, and by the sick and wounded soldiers sent home from the seat of war in Thrace. When Adrianople capitulated in the spring cholera broke out among the captive Turks, the infection extending also to the Bulgarian captors. The condition of the respective camps was extremely insanitary, and we have the authority of the special correspondents of the London papers for the statement that thousands of persons were attacked and that many died; how many will probably never be definitely known. Cholera did not become widely epidemic in the Balkan States until the summer months; up to October 10,937 persons had been attacked in Bulgaria, of whom more than 3500 died; in Servia from July till October nearly 7000 cases were reported, of which about 3000 proved fatal; and in Roumania from August to October 5656 attacks were notified, 2908 of which had a fatal termination. Cholera broke out in Greece at the Piræus among a batch of Bulgarian prisoners, and it was currently reported that the Greek army had also become involved. Cases, too, occurred in Macedonia, particularly in Salonica, whither many refugees had flocked and where many sick and wounded had been sent. Cholera also appeared in Bosnia and Herzegovina during the autumn, and the infection spread to Hungary (630 cases) and Croatia-Slavonia (494 cases), as well as to several towns and districts in Austria, including Vienna, Marienbad, and Prague, but there was no epidemic in the last-named towns. In Russia some cases of cholera from Constantinople occurred at Odessa early in 1913, but the infection did not then spread. During August, however, a number of places in the government of Kherson were invaded by the malady, including the port of Kherson, where 40 cases were notified. Some attacks also occurred in Odessa in September, as well as in several localities situated in the governments of Poltava, Bessarabia, Taurida, Ekaterinoslav, and Kieff. At the close of 1913 the disease seems to be subsiding with the advent of wintry weather, but there is danger that in the coming year a recrudescence of cholera in South-Eastern Europe may occur if sufficient precautions be not taken.

Plague in India.

Up to the end of October, 1913, more than 200,000 cases of plague had been notified in India, and of these upwards of 171,000 had terminated fatally. The provinces which had the highest plague mortality during the ten months in question were the United Provinces of Agra and Oudh, with more than 88,000 deaths; the new province of Bihar and Orissa, with over 25,000 fatal cases; the Punjab, with nearly 19,000; and the Presidency of Bombay, with not far short of 19,000. The epidemic of 1913 reached its height in March and April, and to those two months more than 90,000 deaths from plague were referred. There is a great probability that the year 1913, when completed, will show a considerable reduction of the plague mortality in India as compared with 1912, when 306,088 deaths were registered from the disease, and 1911, when no fewer than 846,873 victims were certified to have perished from the malady.

Plague in the Far East.

Plague was epidemic in Indo-China, including Annam, Cambodge, Cochin China, and Tonkin; also in the Quan-Tcheou-Wan leased territory, where nearly 1500 deaths occurred. It was fatally prevalent also in the Dutch East Indies, especially in the island of Java, where more than 9000 cases were recorded. In Siam there was an outbreak at Bangkok comprising some 60 fatal cases. Plague was widely diffused over China, many cities, districts, and ports being invaded by the infection. At Amoy about 300 deaths were recorded; in Hong-Kong the annual epidemic included 335 fatal cases, and there was an epizootic among rats. Shanghai, too, yielded cases both in man and in the rat; and at Canton in April and May plague caused 270 deaths. Other places attacked were Swatow, Fungshan, Ampo, Kityang, Chao-Chow-fu, and Pakhoi; at this last-named port 2000 persons lost their lives from plague. Chao-Yang was also invaded, and coincidently an unusual mortality was observed among rats and mice. In Japan some cases occurred in the latter part of the year at Yokohama, and there were 140 cases notified in Formosa. In the Philippine Islands the disease continued to crop up in sporadic fashion at Manila during the year, a few infected rats being also discovered. Scattered cases, too, came under notice in the Hawaiian Islands, where also some plague-stricken rodents were found.

Plague in the Near East.

The annual outbreak occurred at the Hedjaz port of Jeddah early in the year, among the victims being the registrar of the British Consulate. At Aden 80 cases and 58 deaths occurred, and the disease was also reported to be present in the Sultanate of Oman. In the Persian Gulf plague appeared at the port of Bushire in April, and the malady was epidemic in the two Persian provinces of Kermanshah and Khorassan from May to September. A few cases occurred at the port of Basra, probably imported from Bushire. In Asia Minor plague cases were reported at the ports of Adalia and Trebizond, and in the Lebanon district.

Plague in Africa.

In Egypt up to the end of November 649 plague cases had been notified, 95 being referred to Alexandria and 25 to Port Said. At the Italian port of Massowah on the Red Sea coast of Erythrea an outbreak occurred in May comprising more than 50 cases. In British East Africa plague was prevalent during the first half of 1913, nearly 260 cases being notified in Mombassa, Nairobi, Kisumu, and other places; many infected rats were also found. In the Muanza district of German East Africa 236 fatal cases of plague were reported, and there was a coincident epizootic among rats. On the island of Mauritius up to the end of November 280 cases of plague had been notified and about 400 infected rodents had been discovered. In Morocco the disease occurred at Mehedia, Casablanca, at Rabat, and El Arish. In Tripolitania plague cases were reported at Tripoli and Derna. In the Canary Islands, at Santa Cruz de Teneriffe some fatal cases were registered during February.

Plague in Europe.

There was very little plague in Europe during 1913. In Russia about 30 cases were notified in the territory of the Don Cossacks; and in the government of Astrachan, in a region said to be an endemic centre of plague, a number of cases

mostly of the pneumonic type were reported. During August 10 cases were registered in Greece at the Piraeus, the infection being traced to Egypt. Later the disease appeared in Athens, but did not spread. A single case was landed at the Austrian port of Trieste in November from the s.s. *America*.

Plague in North and South America.

In California, where the ground squirrels are known to be suffering from enzootic plague, two human cases, both fatal, were reported in 1913; and at Seattle, in the State of Washington near the Canadian boundary, nine plague-infected rats were discovered in November. In South America some 400 cases were reported in the State of Ecuador, chiefly at the seaport town of Guayaquil, and later reports state that the disease was spreading into the interior. The information available from Peru is extremely meagre, but it is known that plague was prevalent, especially in the departments of Lambayeque, Lima, and Libertad, and that more than 530 cases had been notified. The reports from Chili are also very scanty, but the disease was known to be prevailing in Iquique and other places. The government officials in the Argentine do not publish news respecting exotic disease, but consular reports show that plague had occurred at Rosario and in its vicinity, as well as at different places in the provinces of Tucuman, Parana, Cordoba, and Entre Rios. In July it was reported that plague was present in Montevideo, the capital of Uruguay. Sporadic cases occurred in Brazil at Rio de Janeiro, some 36 notifications being received up to October. About 20 attacks were certified at Port Allegre. There was also an epidemic of plague at Bahia, about 150 cases being notified; and at Pernambuco about half a dozen fatal instances were certified.

Yellow Fever on the West Coast of Africa.

During 1913 yellow fever appeared in Portuguese West Africa at Kiusembo, and there was a sharp outbreak at Accra, in the Gold Coast, where cases continued to occur from March to October. Among the Europeans attacked at Accra were the wife of the Governor and his aide-de-camp; cases also occurred in the Gold Coast colony at Quitta and Cape Coast. In September the presence of the disease was reported in the German Protectorate of Togoland, at Lome, where cases had occurred during the previous year; also at Dakar in French West Africa in November. In Southern Nigeria yellow fever became prevalent at Lagos in March, the prevalence extending to other places in the colony, including Wari, Ibadu, Yoruba, Forcados, and Abeocuta; a single ship-borne case was landed at Calabar in October. At the request of the Governor, Dr. H. SEIDELIN, of the Liverpool Yellow Fever Bureau, was despatched to the colony to assist in making special researches with a view to the discovery, if possible, of the specific parasite of the disease and to make other investigations. Dr. E. L. JOHNSTON and Dr. J. W. SCOTT MACFIE, in THE LANCET, have reported the finding of the Paraplasma flavigenum in the blood of cases, and also in dogs at Lagos.

Yellow Fever in South America.

Yellow fever, formerly endemic in Rio de Janeiro, the capital of Brazil, has by means of modern prophylactic methods been completely banished from the city except for occasional imported cases from infected ports. But recently in the absence of the disease the enforcement of the measures has gradually slackened. During 1913 some cases were reported among the residents, the origin of the infection not being traced to outside sources. Six deaths were certified up to October, and it is now feared that the endemicity of yellow fever may be re-established in Rio de Janeiro if care be not taken. Other places which suffered in Brazil were Bahia, where 70 cases were notified, among whom was the British chaplain, whose case proved fatal, and Manaos, where 40 deaths occurred. A few cases were also heard of at Pernambuco and Ceara, and a single ship-borne case at Para. In Venezuela some cases occurred at Caracas, and in the republic of Colombia the presence of the disease was reported at Carthagena, the infection having been brought from the interior. Ecuador suffered somewhat severely from yellow fever during 1913, an epidemic occurring in Guayaquil and extending to Milagro, Naranjito, Duran, Bucay, Aqua Piedra, Yaguachi, and Babahoyo.

Yellow Fever in Mexico and the West Indies.

A few cases of yellow fever were reported during 1913 in the province of Yucatan at Merida and Maxcanu. The disease was also epidemic in the province of Campeachy, in the town of that name, from May to October, and also in the port of Carmen in the same province. Some cases were reported at Puerto, Mexico, in the province of Vera Cruz.

The only reported occurrences of yellow fever that have come to our knowledge in the West Indies were some cases in Trinidad and in Cuba; on two occasions a ship with infected persons on board arrived at the port of Habana. The first instance was in July, when the s.s. *Hydra* arrived from Manaos with the captain ill, reporting also that four passengers had died from yellow fever on the voyage. The second instance occurred in August, when the s.s. *Morro Castle* arrived with a yellow fever case on board—namely, a passenger from the infected town of Campeachy, who had shipped on board the vessel at the Mexican port of Progresso in Yucatan.

Small-pox in Europe.

An outbreak occurred in Sweden during April and May at Stockholm, comprising 37 cases, the infection having been brought from Russia. As usual, the malady was very prevalent in European Russia, epidemics being reported in St. Petersburg, Moscow, and Warsaw, and in less degree in Odessa, Batoum, Riga, and Libau. Small-pox often follows in the wake of armies in the field, and this was observed in the Balkans. At Constantinople the malady was epidemic during most of the year and also at Salonica, from which infection was carried by refugees on ships to the ports of Fiume and Trieste, where the infection spread. The occurrence of small-pox was reported in the Austrian provinces of Galicia, Bohemia, Dalmatia, Moravia, Carinthia, and the Tyrol, as well as in some parts of Hungary. Small-pox was severely epidemic in Eastern Servia and other parts of the Balkan Peninsula and in Greece. In Italy cases were notified in some of the large towns, including Palermo, Naples, Turin, and Rome. There were some serious epidemics in Spain, especially in Barcelona and Madrid, and in less amount in Cadiz, Almeria, Seville, Valencia, and Cordova. At Lisbon 123 cases were notified up to September, and a few instances were observed at Gibraltar and in Malta. In Switzerland small-pox appeared in several cantons, including Argau, Lucerne, Zürich, Basle, Grisons, Vaud, and St. Gall. In Germany 84 cases

were notified up to September, 35 being foreigners, mostly Russians. Berlin, Hamburg, Bremen, Breslau, Kehl, and Strasburg furnished most of the cases. In Luxemburg a few instances came under observation, and at Losser, in Holland, an outbreak comprising 34 cases was observed. During the first half of 1913 there were 81 notifications of small-pox in Belgium. It is difficult to get precise information as to this disease in France, but it is known that a fatal outbreak occurred in Marseilles, and that cases were reported in Paris, Nice, Nantes, Limoges, and Toulon.

Small-pox in Africa.

In Egypt more than 2000 cases were recorded up to October, 91 of them being referred to Alexandria and 89 to Cairo. Outbreaks were reported in Algeria, at Constantine and Oran. In South Africa the presence of the disease was noted at Durban and Johannesburg as well as in other places; and outbreaks occurred in Zanzibar and in British East Africa. Small-pox was epidemic in Somaliland and also in Abyssinia at the end of 1912, but no information concerning its occurrence in 1913 has been received as regards either of these countries. A severe epidemic occurred in Mauritius, comprising more than 1000 cases, but not of a very severe type.

Smallpox in America.

Small-pox was epidemic in various parts of the United States in a mild form, and some towns also suffered, including New York, Chicago, and Baltimore. In Canada the same mild type was noted, outbreaks occurring in various provinces, including British Columbia, Manitoba, Ontario, Quebec, and Nova Scotia. Cases were also reported in Newfoundland. In Mexico small-pox was widely epidemic, and its diffusion was no doubt facilitated by the movements of the Federal and revolutionary armies in the field, infection being at times carried by refugees across the Mexican frontier to Texas and other places in the United States; more than 700 cases were noted in Mexico City. Cases of small-pox were reported in Honduras and Costa Rica. In Peru epidemics occurred in Ancon, Callao, Chancay, Huaco, and Lima; and in Chili at Santiago, Valparaiso, and Iquique, as well as elsewhere. In Argentina the presence of small-pox was recorded at Buenos Aires, and a few cases were reported in Uruguay at Montevideo. Brazil frequently suffers from outbreaks of small-pox, and in 1913 the disease was epidemic in Rio de Janeiro (355 cases up to September) and in Pernambuco, where 367 deaths were registered in nine months from the disease; also at Para, Bahia, and Manaos. In the West Indies scattered cases were certified in Barbados, Grenada, and Trinidad.

Small-pox in Asia.

During the first half of 1913 upwards of 75,000 deaths from small-pox were registered in India, the Punjab being the province that suffered most. Prevalences of the disease were reported in the cities of Bombay, Madras, and Calcutta, as well as at Karachi, Rangoon, and Moulmein. Cases occurred in the Straits Settlements, Siam, Indo-China, and the Dutch East Indies, a severe epidemic being experienced in Java. Small-pox was widely prevalent in China in the Eastern and Northern provinces, where little or nothing was done to check the spread of the infection. Outbreaks were observed in Hong-Kong, Amoy, Hankow, Nanking, Shanghai, and Chungking. Several ports and cities in Japan were invaded, including Nagasaki, Yokohama, Kobe, Tokio, and Osaka. The presence of the disease was reported at Vladivostok and elsewhere in the Russian Maritime Province. In Asia Minor small-pox was epidemic in Beirut, Smyrna and Mersina; and minor prevalences were observed in Adana, Damascus, Tarsus, and Trebizond. There was a limited outbreak in Arabia at Aden.

Small-pox in Oceania.

There was a small-pox epidemic of considerable proportions in New South Wales at Sydney, where over 1000 persons were attacked; but the type was of the same mild character as that observed in North America, and this may be accounted for by the fact that the infection was introduced from Vancouver. Cases were also notified in South Australia, Victoria, and Queensland, while over 100 cases occurred in New Zealand. The presence of small-pox in the Hawaiian Islands during the year was reported. The infection was imported by ship into Samoa from Hong-Kong, but the resulting outbreak did not assume any formidable dimensions.

PUBLIC HEALTH.

In noting, under the headings below, some of the outstanding features of the year to be included in a section on "Public Health," we are again forced to reflect on the continued expansion of the subjects which come before those who take part in public health and sanitary administration in this country. The present year has given abundant evidence of this tendency; it has witnessed such new activities on the part of the State as the general introduction of the local "tuberculosis officer," the passing through Parliament of the Mental Deficiency Act, the decision to make Exchequer contributions for general school medical service, the foundation of a new organisation to spend nearly £60,000 a year on medical research, and the appointment of a Royal Commission to advise as to public action for the repression of venereal diseases; while the International Medical Congress itself conspicuously illustrated the growing demand which medical science considers right to make for increased public action in connexion with disease investigation and prevention. Following the practice of previous annual summaries, we have left to a separate section the question of exotic and tropical diseases, in the control of which public health administration based on modern research has produced such striking results in recent years.

Acute Infectious Diseases.

The United Kingdom has been free during the year from any visitation of cholera or plague, save perhaps for an occasional case occurring at sea which has been dealt with at the port of arrival. The issue by the Local Government Board of the second annual return of the chief notifiable infectious diseases for the whole of England and Wales, together with available statistics of mortality, has enabled stock to be taken of the general prevalence of the acute infectious diseases during 1911 and 1912 with satisfactory results, which appear to have continued during 1913. Scarlet fever continues to have a high rate of prevalence, and in the last few months has been conspicuously epidemic in London, Birmingham, Manchester, and other large provincial cities, but its type remains mild, in marked contrast to that with which physicians were familiar 20 or 30 years ago. Reports which have reached us from medical

officers of health show that the ideal of universal hospital isolation of all scarlet fever cases occurring among working-class populations is often found impossible to attain in epidemics of this disease without entailing dangerous overcrowding at the hospitals, and that organised methods of home treatment and nursing are consequently receiving more attention from sanitary authorities than was formerly the case. Diphtheria prevalence, though falling, appears to do so but slowly, and it is somewhat disconcerting that, notwithstanding the proved value of antitoxin and the known advantages of its early administration, the case mortality of this disease, reckoned on notifications, should for the country generally remain as high as 10 per cent.[1] The problems presented by the carrier case to those who have to deal with diphtheria outbreaks, particularly in schools, have been shown by recent discussions[2] to be more complex than was formerly supposed, not only on account of the long persistence of the carrier condition, but also of evidence that the detection of the diphtheria bacillus in throats or noses of school children may at one time or place signify active infective ability, and in other circumstances may apparently not be associated with any infecting power. The returns of small-pox notifications show that this disease appeared during the year at Newhaven and has caused one or two other local outbreaks, all of which have been kept within very small limits. A report by Dr. MATTHEW HAY on enteric fever in Aberdeen brought out some valuable indications of the effect of reservoir storage on a polluted water and the importance of considering paratyphoid infection during enteric fever prevalence. Apart from this, no widespead outbreak of enteric fever due to infection of water-supplies has been brought to public notice during the year, but some instructive epidemics due to milk infection have been reported, including that at Colne, to which we recently referred.[3] The importance and danger of the typhoid carrier to military populations, especially when he has the opportunity of infecting cooked foods, have been admirably shown by Major CUMMINS, R.A.M.C.,[4] in a contribution which deserves full attention in its bearing on the conditions of the civil population. Poliomyelitis, so far as our information goes, has shown comparatively slight prevalence in 1913; the occurrence of minor outbreaks in certain rural districts was referred to in our issue of Nov. 15th.

Tuberculosis.

The prevention and cure of tuberculosis is now recognised as a matter for a national policy, and, in the better sense of the word, for political action. In opening the fifth annual conference of the National Association for the Prevention of Consumption, held at Westminster in August, the Prime Minister referred in hopeful terms to some of the lines on which, from a national point of view, attempts should be made to expedite the rate of the fall in fatal tuberculosis which has characterised the last 30 or 40 years. Mr. ASQUITH laid stress, first, on measures to secure better social and sanitary conditions, and the provision of decent and habitable dwellings; secondly, on the action which local health authorities should be able to take in consequence of the compulsory notification of tuberculosis, all forms of which became notifiable at the beginning of February of this year as a result of the Local Government Board Order of December, 1912; and finally, on the new provision for the treatment of tuberculosis as sanatorium benefit made under the National Insurance Act, and aided by the grant of a capital sum of 1½ millions for the erection of sanatoriums for the entire community. The first two of these measures of national policy can hardly be expected to be greatly accelerated in the space of a few months or years, although the important new duties imposed on medical officers of health as a result of the Tuberculosis Order should give them a new impetus. It is otherwise, however, with the institutional provision for the treatment of tuberculosis, which, with ample funds to draw upon, has undergone rapid development. How considerable the provision made or initiated during the year has been will no doubt shortly be disclosed by official reports from the Local Government Board and other departments which are not available at the time of writing, but there can be no question of the magnitude of the work which local authorities, with the support of the several central offices, have already got through in this direction. As a result of the operation of the National Insurance Act, "sanatorium benefit" for tuberculous cases among the insured population has had in the first instance to be obtained by Local Insurance Committees, as a matter of urgency, through arrangements with practitioners for domiciliary treatment; by making contracts with private or voluntarily supported sanatoriums or hospitals; by arrangements with local sanitary authorities or special hospital authorities for the use of their isolation hospitals, and in other ways. These, however, have been recognised as usually temporary expedients, pending the development, in many parts of the country well advanced, of local schemes of a more permanent kind for the treatment of tuberculosis. The latter have been organised, in most cases separately, by the authorities of the administrative counties and county boroughs, and include provisions available for all classes of the population, the insured, their dependents, and those who are not insured at all. Whatever may be the case with the provision of institutional treatment of other diseases among insured persons, the treatment of the tuberculous insured seems to have been passed on, beyond any likelihood of recall, to the public health authorities, which, as a result of the payments from the Insurance Committees, and large contributions from Government funds, and with the aid of local rates, will attempt to deal with the whole of the tuberculous population of their districts. The Government contributions for this purpose on the one side, and the demands arising from the general compulsory notification of tuberculosis on the other, appear to have removed many of the objections which several important local authorities at first made towards undertaking the new policy, while others, particularly in some of the larger provincial towns, have from the first welcomed it as an extension of municipal work already in existence. The above relates, it should be said, to England and Scotland rather than to Ireland, where the organisation is on a different footing, or to Wales, where the antituberculosis organisation has been placed, not without protest from the sanitary authorities, primarily in the hands of the Welsh

National Memorial Association and the Welsh Insurance Commission, which have worked with much assiduity. In England the development of local administration in regard to tuberculosis has been actively promoted by the Local Government Board on lines which are now well known and have been generally followed. The county or borough is required to provide the necessary staff, a "dispensary" or "tuberculosis" medical officer (who acts as adviser to the Local Insurance Committee) with any necessary medical assistants and nurses; dispensaries of greater or less degree of elaboration are set up as the headquarters of the work of the tuberculosis officer, at which new cases can be treated or passed on to sanatoriums or hospitals, or to which they can return after leaving these institutions; sanatorium accommodation is made available for suitable cases requiring prolonged treatment; and hospital beds are secured for advanced, emergency, "observational," "educational," and surgical cases. The latter may be provided in separate pavilions at isolation hospitals, in a conveniently accessible sanatorium, or in a special hospital, while arrangements with general hospitals for receiving operative and other special cases are also advocated. The whole of the organisation (as distinct from clinical responsibility) rests, as a rule if not invariably, with the medical officer of health, to whose department the new officers are allotted, and close connexion between dispensary work and the execution of the various duties of the medical officer of health under the Local Government Board's Tuberculosis Order of last year is thus aimed at. This connexion is automatically supplied in county boroughs, where the medical officer of health has control over the whole sanitary organisation; but outside these areas, where responsibility is divided between the medical officer of health of the district and the tuberculosis staff of the county, considerable local adjustments appear to be necessary if the desired coördination is to be secured. In London arrangements for the provision of dispensaries have been made by several metropolitan borough councils, and sanatorium treatment has been supplied mainly by the Metropolitan Asylums Board. The importance of identifying this municipal work in future with the great general hospitals and the special consumption hospitals of the metropolis appears to be generally recognised, and some beginnings have been made in this direction. Our advertisement columns have testified to the large number of appointments of tuberculosis officers and resident medical officers of municipal hospitals which have been made during the year in consequence of the developments to which we have been referring. If we may judge negatively from the small number of substantial complaints which have been made in the lay press, and positively from the information at present to hand, these new public arrangements for treatment have been well received by those for whom they are intended, and there is already a large public demand, particularly among insured persons, for their rapid extension.

Much of the official action referred to above was based on the interim report issued last year by the Departmental Committee on Tuberculosis, of which Mr. W. ASTOR was chairman. The committee issued a final report in March, in which other aspects of the question of tuberculosis prevention were emphasised. Special recommendations were made as to the prevention and detection of the disease in child life, and to the importance of dealing with tuberculous milk infection by legislation on the widest possible lines, to prevent milk contaminated by bovine tubercle bacilli from reaching the consumer. The committee also considered that measures for the complete eradication of animal tuberculosis in this country, though necessarily gradual in their operation, should not be regarded as impracticable. Unfortunately, no further progress with pure milk legislation was made during the Parliamentary session. The Board of Agriculture, however, brought into operation in May a tuberculosis order under the Diseases of Animals Acts, requiring the existence of bovine tuberculosis, when accompanied by emaciation or udder disease, to be notified to the local authority, which in that case has the duty of causing a veterinary inspection to be made, as a result of which the animal may be slaughtered. Partial compensation for compulsory slaughter is payable within certain limits, a contribution to local rates for the purpose being authorised by the Board of Agriculture.

Among statistical studies of tuberculosis reference may be made to the observations of Dr. T. H. C. STEVENSON[5] on the disparities shown in the phthisis death-rates on the male and female populations of different administrative areas, a large male excess being characteristic of urban conditions; Dr. W. H. HAMER'S[6] examination of the important influence of migration on the phthisis death-rate; and Dr. A. K. CHALMERS'S[7] study of the rise and fall of mortality from pulmonary tuberculosis in Scotland, which emphasised the much greater decrease that has taken place in tuberculosis mortality among the industrial parts of that country, with its blended population, than that which has occurred in agricultural areas. As bearing on the question of individual or racial tolerance to certain strains of the tubercle bacillus, much attention has been given to the observation of Dr. A. STANLEY GRIFFITH,[8] who found human tubercle bacilli in the milk of a healthy cow which when a four days old calf had been inoculated intravenously with a culture of human origin. A supplementary volume to the final report of the Royal Commission on Human and Animal Tuberculosis, issued early in the year, gave a useful collection of data as to the response of different species of animals to tuberculin tests.

Syphilis and Gonorrhœa.

The reception given at the Seventeenth International Congress of Medicine to Dr. PAUL EHRLICH'S masterly address on Chemo-therapeutics[9] was something more than a tribute to brilliant scientific work; it marked also the growing feeling that the time has come for the use of the new weapons which we now possess for combating syphilitic infection on a large scale, in the hope before long of exterminating it altogether. On the following day[10] the joint session of Sections on Syphiligraphy and Forensic Medicine passed a resolution strongly urging on civilised governments both "confidential notification" of syphilis and systematic provision for the diagnosis and treatment of all cases of the disease. Earlier in the year a movement had been on foot in this country, with which Sir MALCOLM MORRIS was specially

identified,[11] to secure a national inquiry into the extent of the prevalence of syphilis (or preferably of venereal diseases, including gonorrhœa) and the possibility of national action being taken which would be based on the knowledge which we now possess of the causative spirochæte, of the significance and diagnostic value of the Wassermann reaction, and of the curative power of salvarsan and like compounds. The appeal was favourably received by the Government, and a Royal Commission, of which Lord SYDENHAM is chairman, was appointed in October "to inquire into the prevalence of venereal diseases in the United Kingdom, their effects upon the health of the community, and the means by which those effects can be alleviated or prevented, it being understood that no return to the policy or provisions of the Contagious Diseases Acts of 1864, 1866, and 1869 is to be regarded as falling within the scope of the inquiry." The Commission has already held several sittings, and its proceedings will be followed with interest, in the hope of good practical results. The nature of some at least of the considerations which will come before this body was indicated in a report on Venereal Disease, made by Dr. R. W. JOHNSTONE to the Local Government Board and issued in August,[12] which reviewed the information obtainable from military, naval, and civil sources, and indicated the need for concentrating preventive measures which include the provision of skilled treatment which would readily be accepted, at the earliest time, by infected persons. The report was based on an investigation of Poor-law, general, and special hospitals in regard to the provision made for the treatment of venereal cases, and in view of probable developments its suggestions had special importance to those who are responsible for the management of the institutions in question.

Vital Statistics; Additional Census Volumes; New Form of Annual Report of the Registrar-General.

The increasing entry of health questions into public affairs naturally entails growing demands on the statistician, and on those who supply the statistician with his raw material. The issue during the year of further volumes relating to the Census enumerations of 1911 has made available analyses of the figures which are in considerable advance of those made after previous enumerations. Special reference should be made to the eighth volume, which gives statistics of some 8,000,000 "tenements"—i.e., the dwellings or portion of dwellings occupied by private families or persons living separately—in which the numbers of rooms per tenement and of inhabitants per room are analysed for every urban and rural district in England and Wales, and in various aggregations and combinations of these districts, while special detail is given for the larger cities. A notable diminution since 1901 in the proportion of the population living in one room- or in two-room tenements, and a corresponding increase in tenements of three or four rooms was disclosed by the figures as a whole, although they also showed conspicuously the large extent of overcrowding which takes place in dwellings in some of the northern counties. The Registrar-General's Annual Report has for the first time assumed the form of a massive folio, and while this has been a matter of lamentation at the many libraries that have been accustomed to the familiar octavo which has been issued continuously since the first report appeared in 1841, the alteration can be regretted on no other ground, as it has permitted wholesale revision of the scheme of the volume. For mortality purposes the confusing registration areas have gone, and are replaced by the areas of local sanitary administration, so that now a medical officer of health for any district, however small, can at once find separate statistics of the area over which he has charge, including deaths classified on the same basis (the so-called "short list") as that which he is himself required to adopt. Deaths are also allocated as far as possible to the proper area of residence, as a result of special arrangements for "transfer," and other important alterations have been made. The 1911 volume, it should be added, gives for each administrative area a "standardising" or correcting factor for age and sex distribution which is needed for many comparative purposes.

Mental Deficiency Act: Eugenics.

The Mental Deficiency Act has not yet come into operation, but it is necessary here to chronicle its passage, under the pilotage of Mr. MCKENNA, through the last session of Parliament. Its provisions are important and far reaching, as they not only involve the classification of mentally defectives in order that they may be controlled, by guardianship or in institutions according to the needs of the particular case, but also require that the local authorities concerned (county and county borough councils) should themselves take active measures to seek out defectives and make the necessary provision for them, with the aid of exchequer contributions. The Act, besides fulfilling its primary purpose of protecting the community from the results of the mentally defective being uncontrolled, may ultimately have a further result in diminishing the multiplication of defective stocks, and in this sense may be considered a practical advance towards eugenic ideals, such as those which were so well set out by Major LEONARD DARWIN in the address delivered to the Eugenics Education Society in June. On this aspect of public health, reference must be made to progress in studies of heredity in this country, well illustrated by the general address given by Professor W. BATESON to the Seventeenth International Congress of Medicine,[13] and by the work of the late Mr. EDWARD NETTLESHIP.[14]

Housing Problems.

Questions of improving the housing conditions of the labouring classes have received much prominence during the year, and at the time of writing are being specially brought to public notice in connexion with the deplorable conditions under which casual labour is housed in Dublin,[15] and with the "land programme" of the present Ministry, which is understood to include the promise of wholesale provision of cottages for the agricultural labourer. Medical officers of health have found it necessary, in consequence of recent housing legislation, to give a large amount of attention and detailed labour to this part of their official duties. The Local Government Board's special report on "Housing and Town Planning" for 1912–13,[16] issued during the autumn, has shown that the aggregate of local work done in England and

[16] Forty-second Annual Report of the Local Government Board 1912-13, Part II.

Wales under Mr. BURNS'S Act of 1909 has been greater than is popularly supposed. In two-thirds of the sanitary districts in the country action had been taken to condemn houses unfit for habitation or obstructive buildings, and the record of some administrative areas was a particularly active one. Compared with previous years the provision of new working-class dwellings by local authorities in the absence of private enterprise has shown a marked increase in rural as well as in urban districts. In both these matters the progress made has largely been due to the zeal of sanitary officers, which, we fear, has been insufficiently recognised by those in authority. It is to be hoped that the work which local councils have been persuaded to get under way will not be allowed to slacken in consequence of the vista of competing State enterprise which has lately been opened out, until the nature, scope, and probability of the State action have been much more clearly defined. In rural districts the facts all go to show that the principal difficulty which has to be overcome in replacing insanitary and derelict cottages by better dwellings is the cost of the building itself rather than the price of land. Much has been written about the cheap country cottage which has been the subject of various departmental circulars and detailed study in the report of the departmental committee on the equipment of small holdings which was issued by the Board of Agriculture early in the year. It must be confessed, however, that the ideal £100 cottage as a building for permanent habitation on which money may be advanced seems further than ever from realisation.

The provision of block dwellings for the working classes in London and other large cities was made the subject of valuable contributions by Dr. LOUIS C. PARKES, Dr. E. W. HOPE, and others to the Society of Medical Officers of Health,[17] and reference must also be made to a valuable differential study of mortality in age groups in "apartment houses" of different sizes in Glasgow, contributed by Dr. A. K. CHALMERS.[18]

School Hygiene.

When the system of general medical inspection of school children was set up, it was obvious from the first that neither the central nor the local education authorities could long restrict their activities to inspections, and that organised systems of treatment must soon follow. For some time past "clinics" for special purposes, such as defective eyes, teeth, or skin diseases, have been a common part of local school medical organisations, especially in the larger centres, whilst some have gone further and include the treatment of disease generally in the functions of the school clinic. Not long ago local arrangements for treatment were facilitated by grants made by the Board of Education for this purpose and in support of special schools, and in August of the present year it was announced that these grants would in future be extended to cover half payment from exchequer funds of the expenditure of the local education authorities on the school medical service as a whole, the cost of inspection being included. In return for this substantial contribution from national funds new conditions are to be imposed in various matters of organisation and medical reporting. The department also announced its intention of substituting the compulsory inspection of all children between the ages of 12 and 13 for that hitherto made of the "leavers," and of adding to the inspection now required in the case of "entrants" and "leavers" a third or "intermediate" inspection of children aged from 8 to 9.

We have reviewed the reports of numerous school medical officers during the year, and it is unnecessary to attempt any general account of them on the eve of the publication of the annual report of the medical officer of the Board. Reference may, however, be made to the frequent evidence that the scope of the school medical work is being widened beyond the detection of defective organs and the performance of minor operations, so as more and more to include advice on general preventive and curative measures, such as physical exercises, provision of meals, manual training, and improved methods of education. Although it is rather a misnomer, an effort is being made in some places to extend "school medical work" in such a way that it can provide for the care of the child both after leaving school and before its admission. Special schools and institutions for defective children continue to multiply, and in particular are being planned for tuberculous children, a portion of the Government funds for antituberculosis work having been ear-marked for the purpose. The advantage of open-air schools for certain classes of children, especially those suffering from tuberculosis and bronchial catarrh, rickets, and nervous diseases such as chorea, is being increasingly realised in large centres, and was well developed by Sir GEORGE NEWMAN in the Chadwick Lectures given last month at the University of London. As he there indicated, the open-air school movement has led to reconsideration of the whole type of the ordinary school building from the open-air standpoint, and to the provision for the normal child of forms of educational and physical training, the advantages of which have been proved in the case of the weakly and defective.

Infant Mortality and "Child Welfare."

A very valuable contribution to the working literature of medical officers of health has been furnished by the issue of Dr. A. NEWSHOLME'S second report to the Local Government Board on infant and child mortality, in which a most useful collection and classification of facts have been given of the incidence of mortality on different age periods and from various causes in 241 urban areas of England and Wales, comprising three-fifths of the total population. The urban centres, or parts of them, in which excessive mortality occurs are there prominently brought to notice, together with an account of the circumstances and conditions, many and varied as they are, which must be held to be related to their possession of this unenviable distinction. This important report has also, however, made it clear that in recent years and in most urban centres a very substantial saving of child life is going on, and that the decline is not merely to be attributed to meteorological conditions which have been unfavourable to the prevalence of the greatest cause of mortality in infancy—epidemic diarrhœa. It can be claimed with high probability that saving of infant life on a considerable scale has resulted from improved sanitary and housing conditions, from more efficient municipal and domestic cleanliness, from education in hygiene, and lessened intemperance. This good result must to a large extent be credited to the steady application which the sanitary departments of our larger towns have given to matters of daily detail, and to the

[17] Public Health, June, 1913.
[18] Proceedings of the Royal Society of Medicine (Epidemiology and State Medicine), April 4th, 1913.

development of health visiting and "child welfare" work. The latter form of municipal activity is at the present time receiving much attention. It aims at providing parents with advice which will conduce to the prevention of minor ailments, to their prompt discovery, and to the early treatment necessary for the prevention of more serious disease. Infant consultations and other arrangements with this object are already provided in a considerable number of urban centres. Various aspects of infant mortality prevention were discussed at the special congress on the subject held in London a few days before the International Congress and at the Congress itself. Much stress was laid by various speakers on the relations of mortality in the first few weeks of life and antenatal conditions, and the significance in this respect of deaths recorded as due to "premature birth" or "congenital defects." Another important aspect of the question, specially referred to by Dr. W. LESLIE MACKENZIE, is the absence of any sufficient municipal organisation to bridge the gap between the supervision by the public health authorities of the health of the infant, which is exercised up to 1 year of age, and the supervision under which he falls when he reaches the age of 5 and comes under school inspection. A useful circular was issued by the Local Government Board in July showing graphically the extent to which the Notification of Births Act had been adopted in each county in England and Wales, and urging county councils to make the Act applicable to all their constituent districts.

Industrial Hygiene: Factory Act Administration.

Prominent among the questions of industrial hygiene brought before the International Congress was the effect of different forms of dust in causing respiratory diseases. Dr. E. L. COLLIS and others there discussed the distinguishing properties in this respect of animal dusts, such as come from horn, silk, or wool, and are unaccompanied by pneumoconiosis; vegetable dusts, like flour or cotton, which tend to produce symptoms of the asthmatic type; and mineral dusts, which have further to be subdivided according to their physical and chemical characters. In the latter connexion the importance of free crystalline silica in the causation of pneumoconiosis was insisted upon, as also the distinction to be made between this disease and the complication of tuberculosis which so frequently supervenes, particularly where silicious dust is in question. Dr. F. W. EURICH'S account of some of the principal results of the work of the Anthrax Investigation Committee at Bradford, given to the Royal Society of Medicine,[1] showed the progress which has been made in localising the conditions of special danger (particularly to the detection of blood stains) in eastern wools, and in adapting preventive measures accordingly. A Home Office Departmental Committee on Compensation for Industrial Diseases, which reported in July, considered the legal difficulties which had arisen in consequence of the exclusion from compensation of persons who, though not suffering from the symptom of nystagmus, were, nevertheless, affected seriously by clonic spasm of the eyelids and other affections of the eye. The committee advised that these difficulties should be met by officially establishing a new definition, under the name of "miner's nystagmus," to cover the whole group of these eye affections. Dr. T. LISTER LLEWELLYN'S researches into the causes and prevention of this condition were reviewed in our issue of March 1st. The same committee advised that writer's cramp, subject to certain limitations, should be scheduled as a disease of employment for which compensation is payable, but rejected a similar proposition for Dupuytren's contraction among lace makers, where the essential dependence of the disease upon the occupation was insufficiently established. Sir A. WHITELEGGE'S last annual report on factory and workshop administration records the establishment of new codes of regulations for dangerous trades in regard to the weaving of cotton cloth, "bronzing," and the manufacture and decoration of pottery. The last of these codes, established after protracted discussion and public inquiry, made special provision for systematic medical examination of workers, and contained a large number of important hygienic requirements. In this, as in several other trades, the principle has been introduced of controlling the carrying of heavy weights by women and young persons. New regulations for the protection of persons employed in the manufacture of chromates and bichromates of sodium and potassium came into operation in September. Official inquiries were held also as to the measures to be taken to prevent "pitch warts," with the liability to cancer which accompanies them, in course of which the relative harmlessness of ordinary blast furnace pitch as compared with gas-works pitch has been brought out. According to Dr. H. C. ROSS and Dr. R. W. CROPPER, the mischievous ingredient in pitch derived from coal is not the anthracene oil itself, but an impurity in the rough anthracene cake—probably arising from special forms of vegetable life present in the carboniferous period. In connexion with the prevention of accidents, which forms so large a part of factory administration, it may be noted that several official rules now include the requirement that the firms concerned must provide suitable means of removing injured persons and keep first-aid appliances and sterilised dressings. Home Office conferences have been held regarding the unsatisfactory and unhealthy conditions of the labour of women engaged in gutting and curing herrings at Lowestoft, Yarmouth, and other places, with promising results.

Milk, Food and Dietetics.

As was well said by Sir THOMAS BARLOW in the course of his presidential address at the International Congress, cleanliness in the milk-supply, from start to finish, has a far more exhaustive meaning than in days gone by, and the necessity for reforms in current methods of obtaining, distributing, and storing milk were never better appreciated than they are at present. While, however, some progress has here and there been made as a result of philanthropy, private enterprise, or municipal activity, the necessary general reform still waits on legislation. Strong as are the reasons for Parliamentary action,[2] another Milk Bill has been stillborn, and meanwhile municipal authorities which require special powers to deal with tuberculous or dirty milk continue to complain that their action is paralysed. Among reports and papers on the purity of milk and food which have appeared during the year we may perhaps refer to Professor S. DELÉPINE'S address to the Paris Congress of the Royal

[1] Proceedings of the Royal Society of Medicine (Section of Epidemiology and State Medicine), May 23rd, 1913

[2] THE LANCET, April 12th, 1913, p. 1035.

Institute of Public Health on the control over tuberculous milk in Manchester by veterinary examinations, the report of the Vice-regal Commission appointed to consider the scarcity of milk in Ireland and its effects on public health, and the special reports issued by the English Local Government Board on the biological properties of milk and on the bacteriology of food poisoning. The increased cost of foods of all kinds which has taken place during the last eight years is officially computed at about 13 per cent.[3] and shows no signs of abating. Hence the question for the working class of the most economic way of spending money on nutritious and palatable food is increasing in importance, and the subject is receiving attention from public health authorities in many of the larger towns. In Glasgow a valuable report on the diet of the labouring classes has been made in the physiological department of the University under the auspices of the corporation.

The Public Health Medical Services.

The above notes of public health matters during the year necessarily relate to new movements rather than to the results of some of the more familiar activities of the medical officers of the large number of public bodies, central and local, whose functions include public health questions. If the health and comfort of the public are looked at as a whole, a year's progress would be barren indeed without the results of the labours of medical officers who, following well-established lines of work and investigation, have attempted day by day to secure better and more wholesome conditions of living in whatever direction they are able to do so. The new movements, added to the old, are naturally producing great alterations in the conditions of local service, specially marked in the large municipalities and in counties, where the bulk of the daily work has to be undertaken by "assistant" medical officers. The assistant officer hitherto has had reasonable chance of seeing himself later on a principal officer, but it must be admitted that the prospects of those who have lately entered local services as assistants, particularly in the school medical service, are not always encouraging, and the year has given many evidences of the demand which is arising for consolidation or reform of the public health medical services in various directions.

ANÆSTHETICS.

AT the Seventeenth International Congress of Medicine special interest attached to the Subsection of Anæsthesia, for, as the President, Dr. DUDLEY W. BUXTON, pointed out, anæsthesia for the first time was accorded a place in the programme of these international meetings. He contended that the anæsthetist of to-day was guided by a much more robust knowledge of the science of his art, having at his disposal a wide range of methods from which to select. The discussions embraced these methods: spinal and local analgesia; anæsthesia obtained by ether given by the "open" system, by intratracheal insufflation, by nasal and pharyngeal inhalation, by intravenous infusion, or by rectal and colonic absorption and intramuscular injections; chloroform inhalation by dosimetric methods; nitrous oxide with oxygen employed by the Teter method for major surgery; the adjuvant employment of such alkaloids as atropine, scopolamine, and morphine; hedonal and similar drugs introduced directly into the blood stream. The modern anæsthetist has not only to immobilise his patients, but to deal with "shock" in so far as methods of anæsthesia may increase or diminish the effects of trauma. Hence discussions were held in the subsection on "anoci-association" (CRILE), the "acapnia" theory (YANDELL HENDERSON), and on those curious and little-understood group of symptoms variously called delayed chloroform poisoning, acidosis, post-anæsthetic toxæmia. The last-named subject was brilliantly discussed by Dr. WILLIAM HUNTER and Dr. LEONARD GUTHRIE, to the latter of whom belongs the credit for the first clear clinical presentation of this matter in this country. At the concluding discussion Dr. J. F. W. SILK summed up all the preceding work dealing with the selection of the best anæsthetic and most appropriate method of using it, including both local and general anæsthesia. The work of the section focused the present knowledge alike of anæsthesia and of analgesia in a remarkable manner, giving an impetus to the adoption in the country of the newer methods and to the more careful study of continental and transatlantic systems.

Spinal Analgesia.

Professor TUFFIER,[1] one of the pioneers, regards spinal analgesia as best accomplished by an intradural method. He has used stovaine and tropacocaine, but recently has adopted novocaine, a drug which he regards as the safest of the synthetic group of cocaine derivatives. He deprecates the employment of cocaine and the addition of strychnine and suprarenin to the injected fluid. The extradural injection made between the sacral and coccygeal vertebræ Professor TUFFIER thinks is safe, although at present it seems a less valuable method; with this view Mr. C. A. LEEDHAM-GREEN concurs. The relative safety of spinal analgesia and general anæsthesia resolves itself into a comparison less of the methods than of the persons who employ them. The statistics advanced by Professor TUFFIER in favour of the spinal method are those of experts, while those of general anæsthesia are those of individuals who for the most part are both inexperienced and at times careless, while their methods are frequently open to adverse criticism. Both systems, it is admitted, have dangers, but each has its peculiar advantages in appropriate cases. Dr. G. GELLHORN,[2] in reviewing this subject, refers to KROENIG'S 2542 cases without a death, but with two cases of asphyxia which were recovered; in 63 cases GELLHORN, using novocaine with suprarenin, had three cases of incomplete analgesia, six in which ether had to be used, and one case of collapse, another with "air hunger." Vomiting was frequent when the peritoneum was opened; he had one case of intractable headache. SELLHEIM reported 1000 cases and one death. This percentage he regards as so satisfactory as to make the spinal method the "method of election." STRAUB'S and GAUSS'S views, that if the injection is made in the sitting posture the analgesic becomes "fixed," so that there is but slight danger of its travelling into dangerous places, are interesting, although not fully borne out by

[3] Board of Trade Report on Cost of Living of the Working Classes, 1913.

[1] THE LANCET, August 23rd, 1913.
[2] Journal of the American Medical Association, Oct. 11th, 1913.

clinical records. Syphilitics need not be debarred from this method, although GELLHORN has noticed that in their case the amount of cerebro-spinal fluid is markedly lessened. DOEDERLEIN and KROENIG consider cardiac and pulmonary sequelæ to be less frequent after spinal than after general anæsthesia.

Dr. W. W. BABCOCK,[3] reporting 5000 cases, has chiefly employed stovaine. He reviews the physiology of the method. Stovaine applied to the floor of the fourth ventricle in the medulla of dogs stops respiration, but it is recoverable by artificial respiration. He regards artificial respiration as the correct method for resuscitation. Pre-existent shock is a contraindication to spinal injection since shock is increased by it, although the shock incident to the operation may be diminished. He finds that blood pressure falls in high injections and that interference with respiration occurs. He gives stovaine, 0·08 gramme; acetic acid C.P., 0·2 c.c.; alcohol C.P., 0·2 c.c.; distilled water, 1·8 c.c. Cyanosis is a danger signal. The preliminary use of alkaloids, although increasing the danger of respiratory failure, lessens nausea and vomiting. He prefers the method for operations in the lower abdomen and for cases of acute infection of the peritoneum. He considers that neurotics are unsuitable for it, as they often believe that spinal degeneration is developing and attribute it to the lumbar puncture. CHAPUT[4] points out that in persons over 40 the intraspinous ligaments are often calcified, and so a lateral puncture or incision through the structures under ethyl-chloride spray is necessary. He withholds food from the patient, giving him chloral hydrate and bromide of potassium half an hour before the puncture. He excludes children under 12, the aged, and those seriously ill, from the use of spinal methods. On the other hand, Mr. TYRRELL GRAY, speaking at the Congress, strongly advocated spinal analgesia for even very young children, and in a wide experience had seen no danger. M. DIMITRION and M. SAGHIESCO,[5] in their practice in a Roumanian military hospital, have adopted Jonnesco's high puncture, using small doses of stovaine, 0·03 to 0·04 gramme. If they fail to enter the theca at the first attempt the patient is sent back to bed for four or five days. K. VOGEL and A. KRAEMER[6] report a curious result of spinal puncture, severe vagal disturbances with bradycardia in a man aged 75. Tropacocaine was used. Professor J. T. J. MORRISON (Birmingham) in his Ingleby lecture,[7] gives his experience with tropacocaine in 1295 cases. He refers to syncope as common, and finds that incontinence of fæces may persist for weeks owing to paralysis of the sphincter. In two cases artificial respiration was called for, both being injections in the tenth dorsal interspace for operations on the liver. In one tracheotomy was necessary owing to paralysis of the diaphragm. In 5 per cent. severe headache; in 10 per cent. it was present, but less severe. There was one death, that of a patient in a very serious condition, in the series. Papers by Dr. FREEMAN ALLEN[8] on spinal analgesia and by Dr. W. S. CARTER[9] on the effects of intrathecal injections of Ringer's solution under varying pressures and in varying quantities should be noted. Large injections produced dangerous phenomena. After such injections atropine raised the blood pressure and cocaine stimulated the respiratory centre.

BEDESCHI[10] reports the results of 924 spinal stovainisations. Dose 4 to 7·5 centigrammes; average length of analgesia 40 to 45 minutes. In one case, as a result of inverting the patient, the analgesia reached to the top of the head. He found that when a patient who had had a spinal injection required further operation within a few days he needed a larger dose of stovaine to produce analgesia. If this observation is confirmed by other workers in this line it would suggest that the effect of stovaine is physical and persistent and not a mere transient interference with function. Pallor, sweating, partial failure of respiration and circulation, nausea and vomiting, and rectal incontinence (30 per cent.) are reported. In two cases severe collapse occurred; headache and retention of urine (10 per cent.) with persistent paralysis of the sphincters are noted among BEDESCHI'S cases, and he regards these accidents as detracting from the value of the procedure. Dr. W. S. BAINBRIDGE'S[11] record of spinal work is interesting; it consists of over 1000 cases. He used stovaine or tropacocaine in solutions approximately equal in density to that of the cerebro-spinal fluid. Seven cases of more or less serious after-effects and two deaths were noted. One death was attributed to lymphatism and one to the effect of "pathological conditions"—atheroma, cardiac, renal, hepatic, and pulmonary disease. As these conditions are commonly urged as contra-indicative to general anæsthesia and indicative to the use of the spinal method, it is noteworthy that even that system appears to be open to similar limitations as are the older methods.

Sacral analgesia is discussed by Dr. SCHLIMPERT.[12] He describes the technique. Veronal is given both on the night before and in the morning before the operation, while scopolamorphin or scopola-narcophin is ordered three hours before the puncture, since it is contended that scopolamine has an amnesic effect. The dose is lessened in the case of the cachectic. The patient lies on his side or in the knee-elbow posture. The pelvis is raised and the lower opening of the sacral canal is chosen, its position being marked in the hiatus canalis sacralis by the cornea sacralia. A hollow tube carrying a sharp mandarin is introduced, care being taken to avoid wounding the veins. The sense of resistance enables the operator to judge of his success. If a swelling follows the injection the fluid has gone into the loose tissues and not into the canal. This method is only serviceable for brief operations; it does not always give relaxation of the abdominal muscles and is inappropriate for fat persons. Novocaine and suprarenin in saline are employed for the injection.

Local Analgesia.

Professor HEINRICH BRAUN reported to the International Medical Congress on this subject. He showed pictures of his methods whereby every superficial area of the body can be injected, and further demonstrated how to apply his methods to the deepest regions. These methods had been rendered possible owing to the supersession of cocaine by the safer synthetic novocaine and by the introduction of suprarenin. Ischæmia is produced by the adrenal derivative, so that little of the analgesic is required. The adoption of a regional method made it possible to block

all sensory conduction from the traumatised tissues. The details of Professor BRAUN'S technique are accessible in the third edition of his "Lokal-anaesthesie," which has been recently issued. For infiltration he used 0·5 per cent. novocaine with suprarenin, and for conduction analgesia a 1 per cent. to a 4 per cent. of novocaine with suprarenin according to the tissues to be acted upon. Mr. LEEDHAM-GREEN, although restricting his practice within narrower limits, accepted Professor BRAUN'S statements as being in consonance with his own experience. With novocaine he was satisfied, but his use of hydrochloride of urea and quinine had not been so successful. Dr. EARLE[13] records a case of serious sloughing after the use of this analgesic compound. Professor BRAUN[14] suggests injecting the brachial plexus as it passes over the first rib by means of novocaine and suprarenin, for fractures and dislocations of the shoulder and arm. For the lower limb he relies upon injections made at the site of injury; these must be multiple and varied in direction. In the case of the hip-joint long needles are required to inject into the structures around as well as into the acetabulum. A 1 per cent. strength of the solution is said to be sufficient. The anterior superior iliac spine is the guide to the acetabulum in cases of dislocation, the needle being passed behind this point and kept against the bone until it enters the cavity. He claims that the muscles become relaxed so that reduction is rendered easy. KULENKAMPFF[15] adopts the following method of analgesing the brachial plexus; 2 per cent. novocaine solution with suprarenin is injected, while the patient sits up with his head supported. The subclavian artery is felt for above the clavicle, and a superficial infiltration is made immediately outside—i.e., opposite the middle third of the clavicle. The finger pressing inwards and backwards will make the first rib perceptible, as well as the cords of the plexus passing over it. The needle is made to enter at this point, and if the patient experiences tingling the cords are carefully injected. If no tingling is felt the needle must be partly withdrawn and its point moved backwards and forwards until a cord is struck. W. F. NEIL and F. CROOKS,[16] in 40 cases, only failed to reach the plexus four times. That there is some danger is shown by the experience of A. E. STEIN;[17] he failed to reach the plexus but damaged the phrenic nerve, paralysing the diaphragm, and causing very severe neuralgia. Useful papers on this subject are those of Dr. J. F. MITCHELL[18] and Dr. F. ROOD.[19] CARL DEUTSCHLÄNDER[20] discusses methods of obtaining analgesia of joints. It is essential to empty the joint tissues of blood which can be done by the use of BIER'S method. This accomplished the injection is made into the joint, not into the synovial membrane. The plan fails when the synovial membrane has been destroyed by disease, as no absorption can take place. Injections into the great sciatic nerve are made, according to P. BABITSOKI,[21] without difficulty. The finger is introduced into the rectum, and the needle, which pierces the gluteal muscles towards the ischial spine, is felt and guided to the nerve which passes beneath the pyriformis muscle. The method of Wilm for analgesing the pelvis is described by FRANKE and POSNER.[22] The patient is placed in the lithotomy position, a needle 12 to 15 c.m. long is introduced in front of the anus in the long axis of the trunk until a resistance (the levator ani) is felt. The finger in the rectum feels the ischial spine and guides the needle to the pelvic border of the bone. The needle is partly withdrawn and reintroduced for 2 to 3 c.m. just to the outer side of the ischial spine and 10 to 15 c.c. injected, which should parese the internal pudic nerve. The other side is then done, subsequently the structures between the rectum and prostate, and, last, the subcutaneous tissues. G. MAHÉ and P. VANEL[23] suggest that to obviate the dangers of suprarenal extracts in dental surgery they should be replaced by peroxide of hydrogen. Five volumes of peroxide and five of either a 1 per cent. cocaine solution or 4 per cent. novocaine are slowly injected until blanching of the gum appears.

Recent Methods of General Anæsthesia.

Ether.—Dr. R. H. FERGUSON (New Jersey, U.S.A.), dealt with the Open Ether Method[24] and demonstrated the value of a true drop method, using a mask (Dr. Ferguson's design).

Intravenous ether infusion. — Professor BURKHARDT (Nürnberg) opened the discussion. The veronal series (hedonal) he regards as less safe than the fatty acid series, and chloroform (he uses 0·97 per cent. in saline) is less safe than ether (he uses 5 per cent.). Isopral he suggests as a means for "introducing" ether; as soon as the patient is unconscious the isopral solution is succeeded by the ether. Renal complications do not in his experience of 600 cases follow ether infusion unless there is pre-existing nephritis. Asphyxia is due to the unduly rapid entry of ether. He regards the existence of a high blood pressure as a contra-indication to the method. Professor KÜMMEL extolled this method, speaking from a long experience with its use. W. F. HONAN and J. W. HASSLER[25] have used intravenous infusions of ether (5 per cent.), hedonal (0·75 per cent.), also a mixture of ether (3 per cent.) with paraldehyde (2·5 per cent.).

Intravenous infusion of hedonal. — Dr. Z. MENNELL[26] is convinced that although hedonal has many shortcomings it is valuable and chiefly in brain surgery, provided the narcosis is kept very light—i.e., the skin reflex active—and only small quantities employed. He deprecates its employment in all operations upon the air passages. SEUKEVITCH reports 100 cases[27] of hedonal given per rectum as a preliminary to chloroform. It is dissolved in water and alcohol and is readily absorbed.

Intravenous infusion of paraldehyde and other drugs.—H. NOEL and H. S. SOUTTAR[28] employed a mixture of paraldehyde and ether, 5–15 c.c. of each in 150 c.c. of a cold 1 per cent. solution of sodium chloride in distilled water *free of dead bacteria*, or, failing this, an ordinary boiled tap-water. The solution must be clear after being shaken. They employed the salvarsan apparatus of Fildes and McIntosh, and introduced the needle direct into a vein. The temperature of the mixture must be below 25° C. They regard the method as of value for brief operations. The duration and depth of

narcosis depend upon the dose. Mr. O. ATKEY,[29] using this method, infused a patient suffering from tetanus with paraldehyde and copious injections of saline.

Intratracheal insufflation of ether.—Professor S. J. MELTZER,[30] to whose extremely able report THE LANCET has already referred,[31] opened the discussion upon this subject at the Congress. He detailed the physiological experiments done by him and Dr. AUER which initiated the intratracheal method for etherisation. The method produces intrapulmonary plus pressure, rendering operations on the lungs possible without the production of artificial pneumothorax. The method also by limiting the respiratory excursion facilitates abdominal operations. The effect of the force of the return blast of air is to prevent completely any aspiration of fluids from the mouth or nasal passages into the lungs. The danger of traumatic emphysema of the lungs is obviated by interpolating a safety valve of mercury between the supply tank and the tube feeding the intubating catheter. If, as is usual, the maximum pressure is fixed at 22 mm. Hg, this valve automatically allows the escape of the air-ether mixture, preventing any excessive intrapulmonary pressure.

Dr. F. J. COTTON with Dr. W. M. BOOTHBY [32] fix the limit of intrathoracic pressure at 15 mm. Hg. Dr. MELTZER states, however, that a much higher pressure is safe although not desirable. It is essential, they say, that the patient should be deeply anæsthetised by some inhalational method before the catheter, usually of the French gauge 22 or 23, is introduced by the aid of direct illumination. The head should be slightly extended with the tongue drawn forward; this allows the epiglottis to be drawn out of the way, so the catheter passes easily into the larynx. If it enters the œsophagus and the stomach is distended the viscus must be emptied before withdrawing the catheter. Since ether boils at 96·5° F., if it is heated to this temperature ether vapour will pass into the lungs with dangerous effects. They deny the advantage claimed by Dr. GWATHMEY of superheating the ether-air mixture. The results of experiments upon cats are cited in elucidating the effects produced by the method. They conclude: (1) This method is the only safe one which ensures competent lung ventilation without thoracic movements; (2) hence its value for operations which *per se* interfere with the normal mechanism of respiration; (3) thus its value in intrathoracic operations and those upon the mouth, jaws, tongue, and upper air passages; (4) an ether-air mixture, the supply of which is controlled by a foot pump, is the best anæsthetic, although the nitrous oxide-oxygen mixture with minimal quantities of ether is indicated in some cases; and (5) a safety-valve preventing intrapulmonary pressure exceeding 15 mm. Hg is absolutely essential. Dr. C. N. PECK [33] gives his experience of the method in 412 cases. He met with six cases of lung complications occurring after the operation. Dr. SAM ROBINSON,[34] in reviewing 1400 cases, records seven deaths in patients who were in a very serious condition at the time of the operation. He asserts that the use of too small a catheter leads to persistence of the thoracic movements, and even to aspiration of fluids from the mouth. A useful and practical paper by Dr. CHEVALIER JACKSON [35] describes the technique of passing the catheter into the larynx. Various forms of intratracheal insufflators were exhibited at the Congress in the Subsection of Anæsthetics [36]—viz., those of Dr. Elsberg, Mr. Kellv, Dr. Shipway, that of Mr. Boyle,[37] which is simple and easily worked, and that of Dr. Ehrenfried (Boston), an apparatus which fulfils the desiderata given by Dr. BOOTHBY and Dr. COTTON. Dr. Janeway's apparatus was demonstrated by Dr. NAGLE, and is an excellent one; he gave his experience, a favourable one, of 300 cases.

A valuable paper of experimental research into the percentages of ether vapour during anæsthesia, by Dr. W. M. BOOTHBY,[38] is worthy of reference.

Nitrous oxide and oxygen in major surgery.—Dr. TETER'S full presentation of the advantages of this plan before the Congress focuses the knowledge we possess of the method. His improved apparatus makes a prolonged anæsthesia possible. He advocates some rebreathing, insists on warming the vapours, and upon accurate control over the pressure of the gases and upon the quantity which passes in a unit of time. Mr. H. M. PAGE, who has employed the method in this country, contributes a paper to the Royal Society of Medicine.[39] Papers may be noted by H. FAIRLIE,[40] H. G. SLOAN,[41] S. LEIGH,[42] C. S. HURST,[43] R. C. COBURN,[44] and E. H. EMBLEY.[45] This last named paper gives some important experimental work anent this method and shock. Dr. SKEEL [46] and THE LANCET of Feb. 1st criticised adversely the method in question.

The use of alkaloids, either replacing or as adjuvants to general and local anæsthetics, was discussed at the Congress by Dr. GAUSS (Freiburg), Dr. W. J. MCCARDIE (Birmingham), and Dr. GIUSEPPI, while Mr. L. E. C. NORBURY and Mr. A. F. MORCOM have published their experience.[47]

Anoci-association and shock.—Dr. CRILE'S vigorous exposition of his views has appeared fully in THE LANCET [48] and Professor YANDELL HENDERSON'S views upon the importance of preserving a normal CO_2 content in the blood are too well known to need detailed description of his acapnia theory. Dr. SEELIG, Dr. TIERNEY, and Dr. RODENBAUGH [49] give valuable experimental data on this point.

Chloroform.—Dr. DUDLEY BUXTON'S report upon the dosimetric method was published in THE LANCET of August 16th, p. 464.

Toxæmias associated with anæsthetics.—Besides the important pronouncements of Dr. W. HUNTER and Dr. L. GUTHRIE and of Mr. TYRRELL GRAY made at the Congress, and reported in THE LANCET, a valuable paper by Dr. J. E. PIPER has appeared in our pages.[50]

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

The record of the medical department of the Royal Navy continues, we have reason to believe, to be one of contentment regarding the essential conditions of service. The retirement of Surgeon-General Sir JAMES PORTER, K.C.B., from the position of Director-General, at his own request, was a great loss to the Royal Navy. He had proved a capable head of the medical department during a period of transition, and considerable advances in the organisation and nursing arrangements of naval hospitals were effected during his term of office. He has been succeeded by Surgeon-General A. W. MAY, C.B., who has served with distinction in the Egyptian and Soudan expeditions of 1882–85, and throughout the whole course of the Boer war.

The recently established medical college at Greenwich continues to fulfil the expectations formed as to its efficiency and popularity. The proximity to the centres of medical thought and training in the metropolis cannot fail to have a good effect and lead to a general advancement of the standard of professional efficiency, such as has been so noticeable in the kindred institution of the military medical service at Millbank. A portion of the curriculum continues to be carried on satisfactorily at Haslar, so that there has been no breach of continuity in the associations with that historic centre of naval medical training.

The Lords Commissioners have adopted certain recommendations[1] of the Medical Consultative Board made with the object of remedying to some extent the shortage in the medical branch. Some distinct emendations of the conditions of service ought to have the designed effect.

The Honours list for the year includes a K.C.B. conferred upon Inspector-General DUNCAN HILSTON, who has served in the New Zealand war of 1863, and in Abyssinia; and a C.B. for Deputy Surgeon-General W. M. CRAIG. Special promotion has been granted to Surgeon G. M. LEVICK and Surgeon E. L. ATKINSON (to fleet and staff rank respectively) for service in the recent Antarctic expedition.

The death roll has been a short one during the past year. Deputy Surgeon-General J. LLOYD THOMAS had served in the China-Japan war of 1894–95, and was present at the relief of the Peking legations (1900). Serving with the Royal Navy, though not a member of the Naval Medical Service, was EDMUND ADRIAN WILSON, whose death in Captain Scott's Antarctic Expedition led to a widespread and spontaneous expression of affectionate regard and admiration.

THE ARMY MEDICAL SERVICE.

Scientific Research Work.

Sir DAVID BRUCE and his coadjutors on the Sleeping Sickness Commission have continued the study of trypanosomes. Their earlier observations pointed to the conclusion that the organism of the human disease in Nyassaland, T. rhodesiense, is a species related to, but distinct from, both T. brucei and T. gambiense, and that therefore the human trypanosome disease of N.E. Rhodesia and Nyassaland is not the same as that known as sleeping sickness in Uganda and on the West Coast of Africa. The native name "kaodzera" was suggested for this new disease. From the most recent researches, however, it appears probable that T. rhodesiense and T. brucei are identical.

Major W. S. HARRISON has studied streptococcus rheumaticus, and does not consider it to be the cause of the usual form of rheumatic fever. He has found a bacillus resembling that of diphtheria in rheumatic joint fluids and pleural exudations which possibly may be causative. Valuable observations have been carried out by Captain P. J. MARETT on phlebotomus flies (commonly mis-called "sandflies," which belong to the genus Simulium) in Malta. An accurate knowledge of their life-history and habits leads to the carrying out of effective measures of prevention, and much improvement has already resulted from this practical application of scientific research. Major S. L. CUMMINS and Major C. C. CUMMING have been engaged in the differentiation of staphylococci present in vaccine lymph.

An important research has been carried out by Lieutenant-Colonel W. W. O. BEVERIDGE, D.S.O., in conjunction with Mr. J. HARTLEY DURRANT, of the British Museum, on the temperature reached in the baking of biscuits. Army biscuits are liable to become infested with various species of insects, lepidopterous and coleopterous. It was found that biscuits enclosed in tins hermetically sealed and still intact were infested. Consequently either the heat in baking is insufficient to destroy the ova, or moths and beetles gain access and deposit their ova during the processes of cooling or packing the biscuits. It was determined, by experiments with a thermo-couple, that the temperature in the interior of the biscuits reaches 100° or 105° C. during the baking process, and that infestation must take place after baking, during cooling, and before the tins are soldered up. The observers recommend that the biscuits should be rapidly cooled after baking and access of moth prevented. Major S. L. CUMMINS, in his Parkes Memorial Essay on Causation and Prevention of Enteric Fever in Military Service, has recorded a long series of observations and experiments as to the survival of B. typhosus in the excretions, and on the clothes and persons, of carriers and in food. Successful prevention will consist in the discovery and disposal of chronic carriers, the detection of early, atypical, and abortive cases, and in the inoculation of all troops of the expeditionary force during peace time and of all drafts proceeding to the scene of operations during war. Colonel W. H. HORROCKS has continued his experiments on the variation of bacillus typhosus cultivated under certain conditions, especially with regard to the effect of bacteria-free toxins. He has found that B. typhosus may be converted into B. fæcalis alkaligenes: this appears to have no pathogenic effect on the ordinary laboratory animals, and it has not been possible to re-convert this variant into B. typhosus. The treatment of syphilis by intravenous injection of salvarsan and intramuscular injection of mercury has been carried out on an extended scale by Lieutenant-Colonel T. W. GIBBARD and Major L. W. HARRISON with most excellent results. Their observations and record of this therapeutic investigation were communicated to the International Congress of Medicine and were received with great interest and appreciation.

Military Medical Organisation.

No changes of importance have taken place during the past year in the organisation of the medical

[1] THE LANCET, Dec. 6th, 1913, p. 1649.

services. The Secretary of State for War, both in introducing the Army Estimates in the House of Commons and on the occasion of his distribution of prizes at the Royal Army Medical College, alluded to the high standard of health now existing in the British Army and to the good work of the medical service. This good work now meets with recognition, and the result shows itself in the existence of an efficient administration and a contented body of army medical officers.

At the beginning of the year it was announced that the appointment of Director-General, Army Medical Service, would in future be tenable for four years instead of three, as hitherto. Surgeon-General Sir LAUNCELOT GUBBINS will therefore remain Director-General until March 6th, 1914. It has been announced that his successor will be Surgeon-General A. T. SLOGGETT, C.B., C.M.G., at present Director-General of Medical Services in India. The increase in duration of tenure brings this office into line with other staff appointments at headquarters, and is no doubt desirable in the interests of the public service; too frequent changes in high administrative offices are to be deprecated. It has been announced that an increase of hospital accommodation will be provided for the Territorial Force, by establishing 14 nucleus clearing hospitals, one for each Territorial Division, which will form centres for the instruction and guidance of voluntary aid detachments.

Personnel.

On the occasion of His Majesty's birthday a C.B. was conferred on Surgeon-General L. E. ANDERSON, D.D.M.S. in Ireland; and Major E. S. WORTHINGTON, medical officer to the Duke of Connaught, received a knighthood. Lieutenant-Colonel Sir W. LEISHMAN has been appointed Honorary Physician to the King and promoted to Brevet Colonel; and Major R. J. BLACKHAM has received a Companionship of the Order of the Indian Empire. At the Royal Army Medical College Lieutenant-Colonel O. L. ROBINSON has succeeded Major W. S. HARRISON as Professor of Tropical Medicine; and Major C. E. FOWLER has been appointed Instructor at the Aldershot School of Army Sanitation. We note the retirement of Lieutenant-Colonel Sir DAVID SEMPLE, who, as the founder of the Pasteur Institute in India in 1900, and subsequently as the head of the Research Institute at Kasauli, has done such admirable work in the treatment of rabies, the preparation of antisera, and the training of medical men in scientific investigation in India.

The obituary list includes the names of three Crimean veterans, Deputy-Surgeon-General G. SANDERS, C.B., in his ninetieth year; Deputy-Surgeon-General A. S. FOGO, aged 84; and Surgeon-Major ALEXANDER REID, aged 80; also of Deputy-Surgeon-General N. NORRIS, in his eighty-third year, who served in the Jowaki, Afghan, and Nile expeditions. Surgeon-General H. S. MUIR had served in the Afghan campaign of 1878–80, and before retirement was Deputy-Director-General of the Army Medical Department. Major H. C. FRENCH died at the early age of 43. He had served in the South African war, had been awarded the Albert Medal and the Royal Humane Society's medal for gallantry in attempting rescue from drowning in the Straits of Malacca, and had devoted much attention to the prevention and treatment of syphilis in the army. He was Hunterian professor at the Royal College of Surgeons in 1912. Colonel ANDREW CLARK had zealously supported the medical service of the Territorial Force, in which he was Assistant Director of Medical Services. Dr. PHILIP FRANK, though long retired from the Army Medical Service, was known to very many of the older generation, and universally held in the highest regard.

THE INDIAN MEDICAL SERVICE.

Scientific Work.

There is never any lack of subjects for original medical research in the immense area open to the officers of the Indian Medical Service. Of late years plague has held a prominent place in medical literature, and at the beginning of the past year a report was issued, the seventh of the series, on plague in Madras; the inquiry is still in progress. In regard to cholera great success has attended Major LEONARD ROGERS's method of transfusion of hypertonic saline solution, combined with administration of permanganates by the mouth; the same officer has also obtained extremely gratifying results in the treatment of intractable amœbic dysentery by hypodermic injection of salts of emetine. The All India Sanitary Conference held at Madras in November, 1912, under the presidency of Sir HARCOURT BUTLER, was an important gathering of administrators, engineers, and medical men, at which technical questions in each of the two spheres of professional work were dealt with by experts and criticised from all points of view. There can be no doubt that much good will come from such a gathering together of experienced men, accustomed to deal with the management of epidemics, large questions of public health, and problems of administration. Meeting together on common ground, with opportunity for personal interchange of experience and opinions, doctors and engineers and administrators will certainly benefit by the mutual intercourse, with a resulting benefit to the public service and the public health. Plague prevention, water-supply, and sewage disposal were the principal subjects discussed. This conference was followed by another on Malaria, under the presidency of Sir PARDY LUKIS, which lasted three days; questions of epidemiology, prevention and curative treatment were dealt with, also kala-azar and protozoal diseases. A Punjab Conference on similar lines was held at Simla later in the year, under the Lieutenant-Governor of the province, when rural sanitation, the sanitation of schools, and the prevention of malaria were discussed. Major R. MCCARRISON delivered the Milroy lectures in January, embodying his researches on the etiology of endemic goitre, which he believes to be essentially due to a micro-organism. Major E. E. WATERS has investigated the value of the amorphous cinchona alkaloids in malaria, and finds them to be from three to five times as effective as quinine sulphate. It is expected that the laboratories of the Calcutta School of Tropical Medicine will be completed and ready for use next year, in connexion with the Medical College Hospital. A similar institution is being developed at Bombay in connexion with the existing laboratories at Parel. The Indian Government have sanctioned the establishment of a bacteriological institute at Maymyo, the chief hill station of Burma, together with additions to the Pasteur Institute at Rangoon. In place of the Scientific Memoirs by officers of the Indian Medical Service that have appeared during recent years at irregular intervals there will now be published quarterly an Indian *Journal of*

Medical Research, under the editorial supervision of the Director-General, I.M.S., and Sanitary Commissioner with the Government of India.

Organisation.

A new Royal Warrant as to promotion, &c., in the Indian Medical Service was issued in June; important clauses are those declaring that an officer will not be permitted to remain in the service, if during the first three years his retention appears to be undesirable. A lieutenant is eligible for promotion to the rank of captain after three years, after passing an examination and if in all respects qualified and recommended; and similarly, a captain to major, and a major to lieutenant-colonel, is "eligible for promotion if in all respects qualified and recommended," this condition being substituted for the words "shall be promoted." The extension of service to complete 30 years, and obtain the pension of £700 per annum, is now definitely limited to officers who entered before April, 1911. Early in the year medical manœuvres on a considerable scale were carried out at Rawal Pindi, under the Lieutenant-General commanding the Northern army. Considerable difficulty was found in staffing the field ambulances, and the *personnel* of the Army Bearer Corps will probably need to be further developed. Some modifications have been made in the arrangements at headquarters. The Sanitary Commissioner with the Government of India is now placed under the Director-General, I.M.S., except in regard to giving advice to Government on technical questions. He will also now go on tour instead of being permanently located at Simla. Subjects connected with bacteriology and medical research are now directly under the supervision of the Director-General. A new Inspector-Generalship of Hospitals has been created for Bihar and Orissa, to be held by a lieutenant-colonel. The appointment of sanitary commissioners is now in the hands of the local governments; the officers are to have not less than 15 years' service, and their tenure is unlimited. Deputy sanitary commissionerships are no longer restricted to officers of the Indian Medical Service. We understand that a committee has revised the field medical organisation scheme, and the scale of field equipment.

In regard to the examination of medical officers, lieutenants can now go up for promotion after one year instead of 18 months; also, "accelerated promotion" has been extended to the end of the sixteenth year, and already several officers have regained their position in the Army List owing to this alteration.

Personnel.

A brevet majority has been granted to Captain W. T. MCCOWEN, I.M.S., in recognition of his services in the attack upon the Central India Horse, near Kazarun, in Persia, in December, 1911. Sir C. P. LUKIS, Director-General, I.M.S., and Major J. C. ROBERTSON, Sanitary Commissioner, have been nominated additional members of the Viceroy's Council. At the New Year, Lieutenant-Colonel W. J. BUCHANAN and Major W. G. LISTON received the C.I.E.; and on the occasion of the King's Birthday Surgeon-General H. HAMILTON was promoted to K.C.B.; Lieutenant-Colonel JOHN CRIMMIN, V.C., C.I.E., was granted a C.B.; and Lieutenant-Colonel G. G. GIFFARD became C.S.I. Lieutenant-Colonel J. ROBERTS, C.I.E., surgeon to the Viceroy, received a knighthood. Sir C. P. LUKIS has been appointed Honorary Surgeon to the King. Sir RICHARD HAVELOCK CHARLES, G.C.V.O., has succeeded Sir A. M. BRANFOOT, K.C.I.E., as President of the Medical Board at the India Office.

The obituary list includes Surgeon-Major H. M. GREENHOW, in his 84th year, the last of the medical officers of the Lucknow garrison in 1857; Lieutenant-Colonel E. A. BIRCH, who re-wrote Goodeve's "Management of Children in India"; Surgeon-General G. BIDIE, C.I.E., a Mutiny veteran; and Surgeon-General Sir C. COLVIN SMITH, K.C.B., a survivor of the Burmese war of 1852, and of the Mutiny, who was principal medical officer of the Indian contingent in the Egyptian Expedition of 1882. Sir JOHN TYLER, C.I.E., was a former Inspector-General of Prisons, who organised the Indian Section at the Indian and Colonial Exhibition in 1886; he greatly encouraged and developed the manufacturing industries (especially of carpets) of the jails in India.

DENTAL SURGERY.

The subject which has attracted most attention during the present year has been that of periodontal disease (pyorrhœa alveolaris). Two valuable contributions on this question were read before the Stomatological Section of the International Congress of Medicine. In the one, by Dr. ZNAMENSKY, of Moscow, the patho-histology of the disease was fully discussed, the author reiterating his previously expressed views that the first pathological change commences at the gingival margin, and thence spreads and involves the tissues forming the tooth-sockets. The other communication, by Mr. E. B. DOWSETT, was devoted in great measure to considering the question of treatment. In a paper on the Morbid Anatomy of Periodontal Disease [1] the author, Mr. J. F. COLYER, describes the specimens contained in the Museum of the Royal College of Surgeons, and expresses the view (1) that the disease is a progressive osteitis commencing at the margin of the alveolar process; (2) that the disease is purely local in origin and has its immediate cause in the formation of stagnation areas around the teeth; and (3) that the varying density of the bone influences the rate of destruction.

In a well-illustrated article Dr. MATTHEW CRYER [2] discusses the relation of the contraction of the dental arch to nasal stenosis. and expresses the opinion that the effect of the narrow arch is to compress the tongue and force it back into the oro-pharynx, and that spreading the dental arch gives relief to the nasal obstruction by allowing more room for the tongue, which moves forwards and releases the pressure on the soft palate and other structures. In connexion with this question of mouth-breathing Mr. W. W. JAMES [3] describes a simple apparatus which he has found useful for establishing nasal respiration in those cases where the "habit" persists after the nasal passage has been freed from obstruction.

A paper on the opening of the maxillary suture by expansion of the dental arch was published by Dr. H. A. PULLEN.[4] Cases before and after treatment are illustrated, and skiagrams showing the suture are reproduced, the author evidently believing that it is possible to open the suture. Dr. CRYER, whose paper was referred to above, maintains that a widening of the floor of the nose and the suture by expansion of the dental arch is incompatible with the anatomical structure of the parts involved.

[2] Items of Interest, January, 1913.
[3] Proceedings of the Royal Society of Medicine, Odontological Section, April, 1913.
[4] Dental Cosmos, May, 1913.

The excellent results that are obtained from the free removal of septic teeth in children are referred to by Mr. H. LLOYD WILLIAMS.[5] He points out the extreme difficulty of conservative treatment, even if advisable, and insists that in the majority of cases extraction is the only available treatment, and that it should be thorough and systematic and should proceed on the principles (*a*) that the mouth must be made clean and (*b*) that every tooth left must be functional and self-cleansing. Another communication bearing on this question was published by Mr. ST. F. S. J. STEADMAN.[6]

Attention has been drawn by Mr. G. J. GOLDIE[7] to the value of protagulin, a preparation of thrombin, in the treatment of hæmorrhage. The writer records cases showing the happy results that follow the use of this drug.

A communication on Dental Disease in Relation to Public Health was read by Dr. J. SIM WALLACE before the Stomatological Section of the International Congress of Medicine, in which the author in a most able manner reviewed what had already been done and pointed out the directions in which work still required to be done. In connexion with this subject it is satisfactory to note the increased attention that is being given by public authorities to the teeth of school children.

In a paper entitled "Dental Caries and its Prevention" Mr. J. HOWARD MUMMERY[8] gives an able and critical summary of our present knowledge. Another communication on the question of caries has been published by Dr. SIM WALLACE[9]; in it the author discusses the bearing of recent investigation on the causation of dental caries, and refers to some interesting observations of Mr. F. BREESE on the lodgability of foodstuffs in the teeth. This observer has examined a series of children immediately after their meals, and finds that the immunity to caries is intimately associated with a self-cleansing mouth.

In the domain of operative dental surgery attention must be drawn to a paper by Mr. W. W. JAMES on the Treatment of Root Canals,[10] in which he gives in detail the technique that is necessary for carrying out this operation with strict aseptic precautions.

Amongst other contributions of interest attention may be drawn to the following: An Odontome, by Mr. H. W. GRAVES-MORRIS and Mr. J. A. WOODS[11]; the specimen is one of peculiar shape, and is fully described from the histological point of view. The Congenital Absence of the Deciduous Molars and Pre-molars,[12] by Mr. M. H. ABEL. A Case of Actinomycosis following Extraction,[13] by Mr. F. J. PADGETT.

FORENSIC MEDICINE.

The medico-legal cases of the year have been very numerous, but none was of outstanding importance, and only two cases relating to practice under the National Insurance Acts reached the courts. This is because the majority of the issues in which medical men are likely to be concerned under these Acts of Parliament are to be disposed of by Insurance Committees or Subcommittees and by the Insurance Commissioners. The legal question suggested by the case of Titherington *v.* Dunlop, referred to below, is an important one requiring authoritative decision.

THE COURT OF APPEAL.

Heard v. *Pickthorne and Others.*—This was a case falling under the National Insurance Acts. A member of an Approved Society was refused sickness benefit on the ground that he had sent in a certificate from a medical man not on the panel, the society having passed a resolution that "in every instance a certificate from a panel doctor must be sent." The Court of Appeal held that the resolution was illegal and *ultra vires*, and that as the matter was not one of domestic administration, which under Section 67 of the National Insurance Act, 1911, ought to go to arbitration, the plaintiff was entitled to a declaration to that effect.

Woods v. *Wilson.*—This was an interesting case under the Workmen's Compensation Act. The Court of Appeal, one of its members dissenting, reversed the decision of the county court judge in a case in which compensation had been awarded to a widow in respect of the death of her husband. An accident involving crushing of the abdomen had taken place. There had been afterwards perforation of the bowel treated by operation and the existence of appendicitis had been discovered. A second and subsequent perforation had been found by post-mortem examination. The question had been whether death was due to the accident. It was held by the majority in the Court of Appeal that there was no evidence to connect the death with the accident, the law being stated as requiring the establishment of such connexion "by direct evidence or by legitimate inference, and by something more than guess, conjecture, or surmise."

THE DIVISIONAL COURT.

A case stated by magistrates of some importance, in which refusal to permit an operation for adenoids was construed as neglect of a child, was before the Divisional Court. The question of law raised was whether a parent might be convicted of neglect by refusing to provide medical aid for his child, the refusal being to permit an operation for adenoids, which was recommended by a medical man, and the necessity for which in the interest of the child's health had been pointed out to the defendant. The court held that there might properly be a conviction in such a case, and that the parent "not believing in operations" would not excuse him. This judgment may have a far-reaching effect, and it would be well that medical men, especially those in official positions, should bear it in mind.

THE HIGH COURT.

Palmer v. *Hendon Rural District Council.*—This was an action brought by a schoolboy through his father against the rural district council in whose isolation hospital he had been treated for scarlet fever. Rheumatism and endocarditis had followed, these, according to the evidence of the plaintiff, being due to the negligence of the defendants and of their servants, the nursing staff of the hospital. The jury found that the council took reasonable care to provide a competent staff, but that the place where a certain bath, particularly complained of, had been given was unsuitable for bathing a fever patient, and that, except so far as this was concerned, there was no negligence. No damages were awarded. Here, again, the result should

be noted by medical practitioners holding any official position. The tendency nowadays to bring an action against a public body is certainly growing, and it behoves all in authority who are responsible for the administration of public services to see that no working detail is imperfect. Good general intentions will not prevent the award of damages always.

THE COUNTY COURT.

Titherington v. *Dunlop*.—In the Liverpool county court the plaintiff was awarded the expenses incurred by him in engaging a medical man to attend his child when the medical practitioner (the defendant), who was on the panel under the Insurance Acts, did not come in response to a summons to do so. The most important legal issue in such a case is whether, in the circumstances arising out of the contract entered into by medical men on the panel, they are liable to be sued for alleged breach of duty under that contract.

INQUESTS AND CASES IN THE CRIMINAL COURTS.

The Carrying of Pistols.—A dangerous attempt upon the life of Sir EDWARD HENRY, Chief Commissioner of Police, who was severely wounded by pistol shots fired by a taxi-cab driver with an imaginary grievance, called attention to the need for legislation to prevent the promiscuous carrying of pistols—a subject frequently referred to in THE LANCET. No legislation on the subject has, however, followed. Sir EDWARD HENRY'S assailant was sentenced to 15 years' penal servitude at the Central Criminal Court. The actual death of someone in high position, owing to the pistol carrying habit, seems to be needed as an incentive to legislation, but we congratulate Sir EDWARD HENRY on escaping the position of the needful martyr.

The Trevanion Inquest.—The death of Mr. H. C. TREVANION at Hove from veronal poisoning was followed by an inquest, at which a verdict of "Death by misadventure" was returned, no post-mortem examination having been ordered by the coroner. This verdict was quashed and a second inquest was ordered after the mother had obtained the exhumation of the body. After examination and analysis had shown that probably not less than 150 grains of veronal had been taken by the deceased, it was surmised that the poisoning was not accidental. The second inquest had no result so far as attaching blame to anyone for the death was concerned, but the case will be remembered as showing that an inquest is incomplete as long as anything is left to conjecture and opinion which can be proved with certainty by post-mortem examination. The recent scheduling of veronal as a poison has been largely due to the attention drawn to it by this inquest.

ANATOMY.

For the most part the progress of anatomical thought during the past year is summed up in the doings of the Anatomical Section of the Seventeenth International Congress of Medicine. Reports of sectional meetings and a summary of anatomical progress have already been published in THE LANCET, and as a brief *résumé* it may be said that our knowledge of the whole nervous system has been summarised, defined, and extended.

In embryology and morphology much progress was marked, and in anatomy as applied to the practice of medicine the study of the nervous mechanism of the heart rhythm stands out as a subject in which great recent advances have been made. Indications are already showing that somewhat similar lines of research may throw much light upon the debated subject of intestinal stasis and intestinal "kinks." Intestinal kinks will never be regarded by anatomists of wide views as impediments to the passage of intestinal contents, while intestinal stasis, as the result of an impairment of neuro-muscular mechanism, is likely to become an accepted clinical factor. In anatomy as applied to surgery perhaps the greatest agreement has been established in the study of the disharmonies between rib development and the constitution of the brachial plexus; at least one case has been recorded during the year in which the surgeon has removed with success a normal first rib for brachial neuritis.

Although outside the strict province of medicine and surgery, the anatomical year has especial claim to note on account of the discussion waged over the "Piltdown skull." Opinion is still somewhat divided concerning the characters of this relic; and this is wholly satisfactory, for from every discussion there will emerge some facts which may form criteria by which we may judge future finds.

Concerning what may be termed the domestic affairs of anatomy, perhaps the most important change is the complete adoption in the text-books of the Basle nomenclature. The student has become acquainted with this system some 20 years after its establishment, and he is inclined to ask if it is essential, if it is satisfactory, and if it is likely to be permanent. To these questions only partially satisfactory answers can be given. It is not likely that for some years to come the B.N.A. will be the exclusive language of the examination room; the B.N.A. is generally admitted to be somewhat defective; and there is an overwhelming probability that it will undergo some considerable revision before it becomes the permanent nomenclature of English-speaking anatomists.

Another question which may ultimately have great influence upon the progress of the advanced study of anatomy in England has been raised during the year. If the study of advanced anatomy is to progress satisfactorily it is necessary that its teaching be conducted by men whose life-work is devoted to the subject; and it is almost equally necessary that the students trained by them should have their knowledge tested by professed anatomists. This entails the old question as to how far busy practising surgeons are competent to examine candidates in higher anatomy examinations. The inclusion of three practising surgeons (instead of the usual two) on the Board of Examiners for the primary examination for the Fellowship of the Royal College of Surgeons of England has raised this question anew. For the progress of British anatomy it is to be hoped sincerely that next year we may chronicle a wider representation of professed anatomists as examiners.

CHEMISTRY.

The Birth of the Atom.

The most absorbing announcement in chemistry during the year was that made by two investigators who were working quite independently of each other, that they had either achieved clearly and definitely the transmutation of the elements or had forced energy into taking a material shape. The reason for one or the other conclusion was that when hydrogen gas was introduced in small

quantity into an X ray bulb and a rapid and continuous cathode discharge was allowed to pass both helium and neon made their appearance. It remained to determine whether the new gases were the direct product of electric energy, or whether they were merely occluded materials expelled from the bulb, or whether they were transmutations of hydrogen or aluminium (the cathode). The production of neon and helium under the circumstances described does not appear to be disputed, but so far we are without any completely satisfactory explanation of their origin. Further work appears, however, to have cleared up one point, and that is as to the possible part played by aluminium. It is now shown that electrodes are not necessary at all for the production of neon and helium, and so these elements can lay no claim to aluminium being their parent. We are not aware that the other important points we have mentioned have received elucidation, which is somewhat surprising, since the experiments appear to be of a simple character involving not the use of radium but of electric energy. We should have thought that the reward of investigation in this case would have proved so great—the establishment of a principle of colossal significance—as to have stimulated hundreds of workers to pursue the subject. But we are still without confirmation that an atom has been born in these experiments, that the line dividing energy from matter has been withdrawn, or that actual transmutation of the elements has been accomplished. We have advanced far, but the case is not proven yet. Professor NORMAN COLLIE, at University College, London, was one of the investigators, and Mr. H. PATTERSON, of Leeds University, the other. Sir WILLIAM RAMSAY, who has prominently led the way along this path of research, expressed his gratification that the theory of transmutation now no longer rested on his *ipsissima verba*.

A Great Advance in Crystallography.

Early in the year we announced a discovery which must have brought joy to the hearts of crystallographers and to the supporters of the atomic and molecular theory, inasmuch as ocular evidence was obtained which substantiates the modern theory of crystal structure upon the position of the atoms. By passing, for example, the X rays through a crystal an interference photograph is obtained of what is called the space lattice of the crystal. It would appear that crystallography has thus afforded to its sister science chemistry the first visible proof of DALTON'S atomic theory, leading us to a practical knowledge of that hitherto mysterious world where DALTON'S atoms and molecules reign supreme.

Radiations in Economics.

The study of the properties of the ultra-violet rays is leading to some interesting developments. They are now being employed on a practical scale for the sterilisation of water and milk, while more recently it has been shown that the ultra-violet rays can produce changes similar to those effected by enzymes. Thus starch has been converted into sugar and albuminoids into soluble proteins as though diastase and pepsin had respectively been employed.

Active Nitrogen.

It will be observed that chemical research during the year has for the most part received its stimulus from that mysterious agency, electric energy.

That hitherto stubborn element nitrogen has yielded to the potential influences of the electric discharge, with the result that an allotropic form of it has been obtained. This form of nitrogen is extremely active, it combines with itself, returning to the familiar gas, and in the process a beautiful yellow light is emitted which continues until the process of the pairing of the separated atoms is complete. Atomic nitrogen also combines with the carbon of acetylene or chloroform, producing cyanogen compounds, while it forms an explosive combination with mercury. It will be interesting if it proves that this monatomic nitrogen combines directly with hydrogen to form ammonia, as in that case a new development in regard to the production of fertilisers for the soil may be inaugurated.

The Absorption Spectrum of Alkaloids.

The application of the spectroscope to the elucidation of the structure of the alkaloids as well as to their detection and estimation has an obvious interest for medical men. It is the ultra-violet end of the spectrum which is concerned, for there the absorption phenomena of alkaloid solutions are displayed. Ultra-violet rays are employed, and the prisms and lenses are made of quartz as the ultra-violet rays are cut off by glass. The alkaloids prove to have very characteristic spectra, and the lines of selective absorption can be photographed. The minutest quantities of alkaloids can be detected and a permanent impression can be kept of the records which are always available for reference.

Vitamines.

The vitamines have attracted considerable attention during the year, but further investigation is needed before a definite conclusion as to their rôle in foods and in the body can be formulated. A definite substance has at any rate been extracted from rice-polishings, yeast, bran, and milk which forms a small though apparently a very essential part of foodstuffs, inasmuch as their value as nutrients is impaired without its presence. The so-called deficiency diseases appear to arise from the use of foods from which vitamine has been removed. The substance appears to be a pyrimidine base analogous to uracil and thyamine and is probably a constituent of nucleic acid. It is definite enough to be crystallisable, the crystals giving a constant melting point. It is to be hoped that this substance will be the subject of further active researches, for the importance attached to the chemistry of foods seems to diminish in contrast with the vital influence of this remarkable base in dietetics.

CONTRIBUTIONS FROM "THE LANCET" LABORATORY.

During the year the number of preparations examined and reported upon in our analytical columns was 72, which involved 196 analytical determinations. In regard to completed special inquiries the number of analytical determinations was 236. This figure does not include the analyses involved in a special inquiry now in hand, the results of which we hope to publish in a future number. So far over 300 determinations have been made in this investigation.

In our first issue of the year (Jan. 4th) we published an article on Some Kitchen Experiments with Aluminium. This investigation had its origin in a number of inquiries which reached us as to the suitability of aluminium as a material for cooking utensils. A statement to the effect that aluminium was freely attacked by certain foods, which were thus contaminated by the metal

causing injury to health, was widely circulated. A very large number of practical experiments was made with results that may be judged from the concluding paragraph of the report, which was as follows: "We are confident that aluminium, as it is now made by reputable manufacturers, is a suitable material for cooking vessels, and that any suspicion that it may communicate poisonous qualities to food in the process of cooking may safely be dismissed in view of the results of the practical experiments which we have recorded, showing that the metal is not appreciably acted upon in cooking operations." This finding was confirmed subsequently in a report issued by Dr. JOHN GLAISTER, Regius professor of forensic medicine and public health, Glasgow University, and his senior assistant, Dr. ANDREW ALLISON, who summed up their work by saying: "We find ourselves in accord with the conclusions arrived at in that article" (referring to THE LANCET report).

In THE LANCET of May 3rd appeared an annotation on "A Recent Analysis of Asparagus." The presence of a sulphur oil was confirmed, a body which is probably responsible for the well-known peculiar odour of the kidney excretion after a diet of asparagus. A curious fact was observed during the experiments—namely, that when asparagus shoots are left in water for a few days a decided odour of onions is developed. It was further shown that quite 80 per cent. of asparagus is soluble in boiling water, and hence from a nutritive point of view asparagus soup is superior to the boiled shoot. The nutritive value of the entire asparagus is in any case low, the sugars amounting to 3·6 per cent., the proteins to 3·8 per cent., the fibre (in the tender portions of the shoot) to 1·00 per cent., and the mineral salts to 0·80 per cent. The pleasant flavour of asparagus, however, is a factor of undoubted importance in dietetics, as is also the presence of the basic body vitamine.

In THE LANCET of June 14th were reported the results of some experiments made in regard to the measurement of the chemical energy of the sun's rays. The experiments were made during a brilliant spell of weather at the latter end of May and early in June. The sun's rays then were shown to display extraordinary chemical activity. The maximum chemical intensity was shown to occur between 1 and 2 P.M., although the temperature did not appear to reach its highest point in the same interval. It was observed that if the chemical energies of sunlight are concerned in the physiological joyousness of the body, and are really the foundation of the cheerful effect of the bright sunny day, their measurement is clearly of interest and importance.

The question having been raised in our correspondence columns as to the accuracy of clinical thermometers, an independent investigation upon the subject was undertaken in the laboratory. About 150 observations were made under varying conditions with 12 thermometers obtained on the market at prices ranging from 1*s.* 6*d.* to 2*s.* 6*d.* The results showed fairly accurate readings, but the interesting observation was made that at temperatures ranging between 100° and 105° F. the readings in many instances were closer to the actual truth as shown by a standard instrument when the duration of the test was two minutes instead of half a minute. The conclusion that the 30-second thermometers give, generally speaking, more satisfactory results when they are incubated for more than 30 seconds, a two minute incubation giving exact results, has been confirmed by other observers. There are, however, some further interesting points in connexion with this subject which we propose to investigate.

In THE LANCET of Nov. 29th appeared a special article from the laboratory entitled "The Chemistry of a Cup of Coffee," in which it was pointed out that hitherto such analyses of coffee as have from time to time been made and published have referred to an examination of the entire coffee berry, and not to the infusion as it reaches the consumer. The results in this report refer to the composition of the infusion to be drunk, the chemistry of the "grounds" having been left out of consideration. In drawing a comparison between coffee and tea it was shown that while the alkaloid caffeine in coffee is identical with that in tea, yet its associations in coffee are quite different. In tea infusions the alkaloid occurs chiefly as a tannate, which is a compound insoluble in the acid juices of the stomach. In coffee it occurs as an easily soluble compound. Here would appear to be the explanation of the prompt action of coffee as a restorative and stimulant, particularly when employed as an antidote to narcotic poisons. In the same way coffee probably serves to overcome to some extent the narcotic effect of alcohol, and to render a person wakeful owing to its stimulating effects upon the central nervous system. One interesting point brought out in the inquiry was that cold water extracts from the coffee berry as much material as does boiling water, including the whole of the caffeine. On the other hand, cold water extracts from tea less than half of the substances which hot water extracts, and the cold water infusion of tea contains only 17·5 per cent. of the total caffeine present. It was shown that there is practically no relation between chemical composition and quality, but the process of roasting effects unmistakable chemical changes which are seen chiefly in a reduction in the amount of caffetannic acid and in a development of aromatic bodies which give to coffee its æsthetically attractive characters. In conclusion, it was remarked that coffee has no direct food value, but inasmuch as it diminishes nervous fatigue it may serve in this way to increase muscular power.

PHARMACY.

Scientific Work.

The year just closing has been distinguished by several interesting events, and may justly be regarded as one of pharmacy's red-letter years. Matters which at ordinary times would have been regarded as of paramount importance have been inevitably overshadowed to some extent by the novel modifications produced by the National Insurance Act and the consequent rearrangement of a large part of the system of pharmaceutical service. But there has been no diminution in the output of the ordinary scientific work, though this is not remarkable, since the workers in the scientific field are among those least affected by the administrative changes which the Insurance Act has brought in its train. The papers communicated at the evening meetings of the Pharmaceutical Society, at the annual meeting of the British Pharmaceutical Conference, and at the International Pharmaceutical Congress have not,

perhaps, been striking, but they show that a good average amount of work has been accomplished. In a paper read before the Pharmaceutical Society Mr. E. F. HARRISON and Mr. P. A. W. SELF showed that the method employed by the chemists at the United States Customs for the analysis of asafetida was imperfect, and that undoubted samples of genuine asafetida might conceivably be condemned by the process. In a paper on Standardised Powdered Alcoholic Extracts Mr. E. H. FARR and Mr. R. WRIGHT explained a method for preparing powdered aconite extract, the standard for which they suggested should be 1 per cent. of aconitine. A communication of considerable value to medical practitioners was contributed by Dr. H. A. D. JOWETT, in which he discussed the question of the advisability of replacing galenical preparations with their active principles. He showed that while the sole use of active principles, either singly or in combination, is the ideal state of administration of remedies, it is at the present time in the majority of cases impracticable. There are nevertheless cases in which our knowledge is sufficient to warrant the statement that the galenical preparations can be replaced adequately and advantageously by the active principle or combination of principles. On the other hand there are drugs from which the active principles have been isolated and investigated, but about which there is a doubt as to whether these principles represent the full activity of the galenical preparation. Dr. JOWETT'S communication sufficed to show that much investigation remains to be carried out before galenical preparations can be entirely replaced by active principles, and that the work should be carried on by pharmacologists, pharmaceutical chemists, and clinicians working in unison. The results of much painstaking research were contained in a paper on Euphorbia Pilulifera by Dr. F. B. POWER and Mr. H. BROWNING, jun. This drug attracted considerable attention some time ago on account of its reputed value in the treatment of diseases of the respiratory organs; but a thorough chemical examination revealed no constituents to which any specific physiological action could be ascribed, and such therapeutic virtues as the plant has been presumed to possess do not appear to depend upon any single substance of a definite chemical character.

The British Pharmaceutical Conference.

The jubilee of the British Pharmaceutical Conference, an organisation which has played an important part in the progress of pharmacy, was celebrated in London at the end of July, and some 600 members took part in the celebrations. Taken as a whole, the papers were of a high standard, and the majority contained good sound material which will form a valuable addition to the stock of pharmaceutical research. Mr. JOHN C. UMNEY, the president, devoted his address to the subject of the revision of the Pharmacopœia; he showed that in most countries medical practitioners and pharmacists divided the work of revision and shared the credit, and expressed the opinion that in Great Britain pharmacists are not accorded a fair share of the credit. Mr. UMNEY, speaking on behalf of pharmacists as a body, declared that until their work was properly recognised they would have nothing more to do with the preparation of the Pharmacopœia after the next edition is published. He proposed that an Imperial Commission should be appointed, composed equally of physicians and pharmacists, including representatives of both professions from British colonies, and that the Pharmacopœia should be the authoritative work for the whole of the British Empire. Professor VAN DER WIELEN read a communication on the standardisation of opium, in which he suggested that a normal opium should be prepared by mixing opium of four different origins, and showed that in this way the resultant opium would be more constant in strength than one made by adding some inert substance to the drug and standardising to 10 per cent. of morphine, irrespective of the quantities of codeine and the other alkaloids. In a paper on the Chemical Examination of Wheat Germ, Dr. F. B. POWER and Dr. A. H. SALWAY showed that wheat germ contains a very small amount of sinapic acid—a fact of especial interest, inasmuch as this acid has hitherto only been known to occur in mustard seed, or at least in the family of cruciferae. Two useful papers on Thyroid Pharmacy were contributed; in one of these Mr. R. G. GUYER gave the result of the examinations of large quantities of thyroid glands obtained in Scotland, and called attention to the dual standard in vogue in prescribing and dispensing the thyroid gland preparations. He expressed the opinion that as the British Pharmacopœia definitely stated thyroideum siccum as the substance to be used pharmacists should always employ that standard in dispensing. In another paper on this subject Mr. N. H. MARTIN suggested that if an iodine standard was set up for thyroid the standard of 0·25 per cent. would not be difficult to maintain. Mr. E. M. HOLMES, curator of the Pharmaceutical Society's museums, contributed an interesting communication on the Myrrh of Commerce, Ancient and Modern, in which he showed that the general belief that the myrrh of the Scripture was medicinal myrrh is incorrect. Two papers on Extract of Male Fern were communicated, in which the authors, Mr. E. F. HARRISON and Mr. P. A. W. SELF, and Mr. C. A. HILL, suggested methods by which the adulteration of this product could be detected. Dr. F. H. CARR and Dr. H. H. DALE presented a communication on Ergot and its Preparations; the authors suggested that since the chief active principles of the drug had been isolated in a state of chemical purity, it seemed opportune to submit to the test of this new knowledge the pharmacopœial requirements for the drug and its preparations. From this point of view they criticised the pharmacopœial preparations of ergot, and suggested, among other things, that suitable salts of ergotoxine and the fluid extract of ergot of the U.S.P. should be introduced into the British Pharmacopœia and some of the other preparations discarded.

The Eleventh International Congress of Pharmacy.

The Eleventh International Congress of Pharmacy was held at The Hague during the third week in September, and was attended by delegates from about 20 different nations. Reference should be made to the lecture on the Synthesis of Glucosides by Professor BOURQUELOT, of the School of Pharmacy of Paris, who has done so much valuable work in connexion with the investigation of drugs. He gave a most interesting account of his long series of experiments in regard to the action of emulsin on glucosides, and announced that he had discovered that the action of enzymes is twofold—decomposing and synthetic. A committee was appointed to frame a scheme for the establishment of an International

Pharmacopœial Bureau. Another matter of considerable pharmaceutical interest discussed by the Congress was the law affecting trademarks applied to chemical products used in medicine, and it was resolved to recommend that every medicinal substance bearing a trademark name should also bear an ordinary name from the use of which the owner of the trademark would suffer no loss of rights. A proposal to introduce into pharmacopœias a system of international nomenclature was brought forward by one of the French delegates, who suggested that in addition to the national names of drugs, &c., international names should be used which should be either in Latin or Esperanto. After discussion the matter was referred to the International Pharmaceutical Federation.

Pharmacists and National Health Insurance.

Pharmacists began the year less hopefully than they now witness its close. Twelve months ago the operation of medical benefit under the Insurance Act was about to commence, and not unnaturally many people were apprehensive for the future of the craft. Actual experience, however, has shown that while the conditions regulating the pharmaceutical service under the scheme are capable of improvement, pharmacists are on the whole somewhat better off than they were before the Act came into force. The immediate effect of the operation of medical benefit was to increase enormously the professional work of the chemist, and in industrial districts there are many chemists' shops in which hundreds of prescriptions are now dispensed weekly, whereas in pre-Insurance Act days the dispensing of medicines in these shops was quite a subsidiary part of the business carried on. Unfortunately, the sums available for the payment of the drug bill do not allow the Insurance Committee to pay for the drugs on a scale which permits of more than a very small profit, and, what is more unfortunate still, it is probable that in some insurance areas the amount allotted will be insufficient to pay the chemists' bills in full. In such districts panel chemists are faced with the possibility that their bills will have to be discounted, although it is hoped that the Committee will find some means of making up the deficiencies. The tariff which has been adopted throughout the country was drawn up by the Pharmaceutical Standing Committee, a body which has done an invaluable amount of work. Some modifications were made in various districts to suit local requirements, but, generally speaking, the tariff is much the same in all parts of the country. The principle upon which it is based is that of making a charge for each ingredient according to its quantity and value and an additional charge for the time and skill required in dispensing. The tariff has been recently revised by the Standing Committee, and accepted by most of the local Pharmaceutical Committees and Insurance Committees; the new tariff forms the basis of the new contracts which are being made between the chemists and the committees. It will probably be found when the figures for the whole year are available that the average cost per prescription, taking the country as a whole, will be between 7*d*. and 8*d*. In Scotland the chemists are negotiating with the Insurance Commissioners for a small increase in the dispensing fees, the claim for special treatment being based upon the fact that much of the dispensing which is now done on Insurance Act terms was formerly paid for at ordinary prices, a large proportion of private clients having been transformed into insured persons.

Early in the year representations were made to the Commissioners that the requirements of the Act as to the qualification of persons who wished to go on the panels and to undertake the dispensing of medicines operated harshly in some quarters and were to the disadvantage of the insured population generally. A Departmental Committee was accordingly appointed to investigate these complaints, and many witnesses were heard. Evidence was given on behalf of drug-store proprietors to the effect that in certain areas serious inconvenience had been experienced by insured persons in obtaining medicines ordered for them by their doctors, and that this was due to the fact that the panel chemists were unable to cope with the demand. On behalf of the doctors' dispensers it was represented that the provision whereby Insurance Committees were unable to make arrangements, except in special circumstances, for doctors to dispense, part of the work which medical practitioners had employed dispensers to do had been transferred to chemists, and the field of employment open to such persons had been restricted in consequence. With regard to the case of the drug-store proprietors, the Departmental Committee came to the conclusion that such slight inconvenience and delay as was proved by the evidence to have taken place was due to temporary causes which had been removed. Further, the committee expressed the opinion that it would be inadvisable to amend the Act in such a manner as to permit of arrangements for the dispensing of medicines for insured persons being made with persons other than those entitled to carry on the business of a chemist and druggist. If, however, it should for any reason be deemed desirable that persons who are not qualified under the Pharmacy Acts, but have been employed in business as drug-store proprietors, should be permitted to enter into arrangements with Insurance Committees for the dispensing of medicines which do not contain scheduled poisons, the amendment of the Insurance Act necessary for this purpose should, in the opinion of the Departmental Committee, be framed not so as to confer a statutory right, but so as to authorise an insurance committee to enter into arrangements, if it think fit, with persons who are known to the committee to have been *bonâ fide* engaged in business as drug store proprietors. With regard to the case of the dispensers the committee considered that experience as a dispenser to a doctor or to a public institution should not be regarded as in itself and alone qualifying for employment by a chemist and druggist in that capacity. They expressed the opinion that some direct test of actual attainment should be imposed, the chief object of such a test being to ascertain the ability of the dispenser to dispense any kind of prescription such as it might afterwards be his duty to deal with. Short of the qualifying examination in pharmacy there is no test such as that which the committee appear to have had in mind, but it is understood that the Council of the Pharmaceutical Society intends to introduce a Bill to set up an assistants' examination—which would possibly be a half-way house to the qualifying examination in pharmacy—which would be a suitable test for dispensers who intend to deal with insurance prescriptions under the supervision of panel chemists.

At the end of the last Parliamentary session an Act was passed to amend the Insurance Act, one

of the effects of which was to set up pharmaceutical committees in each insurance area. These committees were duly elected towards the close of the year, and it is anticipated that the Pharmaceutical Committees will be able to assist Insurance Committees in such a way as to enable the latter to overcome many little administrative difficulties which were experienced during the first year of the operation of medical benefit. The new Regulations as to medical benefit, which were also issued towards the end of the year, contain provisions which were not in the first Regulations, the effect of which will no doubt be to facilitate the smooth working of the machinery of the Act. Among these provisions is one which sets up in each district a pharmaceutical subcommittee and another which sets up a joint services subcommittee; it will be the duty of these committees to consider difficulties arising out of the drug supply and to suggest means of overcoming them. One of the matters on which the joint services subcommittee will be able to give advice is the question of the prescribing of proprietary medicines, and another that of the dispensing of prescriptions during the hours in which chemists' shops are ordinarily closed. In isolated cases complaints have been made that patients have found it difficult to obtain medicines on the weekly half-holiday, but in order to remove any inconvenience of this kind chemists in the areas affected have very properly made arrangements by which medicines can be obtained at all hours. Should difficulties of this kind arise in future the pharmaceutical subcommittees and the joint services subcommittees would no doubt be able to suggest means of removing them.

Pharmaceutical Organisation.

It has become evident that some change in the system of pharmaceutical organisation will be rendered necessary as the result of the working of the National Insurance Act. Fortunately, the Pharmaceutical Society is in a very healthy condition, and is stronger in membership than it has ever been before; it has been shown to be capable of linking up the local pharmaceutical associations throughout the country, and of directing their energies in the proper channels. Mr. W. J. U. WOOLCOCK, who succeeded Mr. RICHARD BREMRIDGE as the society's secretary, had proved himself a valuable organising officer before his appointment, and since then his services to pharmacy have been more valuable than ever. If it should be found desirable to federate the Pharmaceutical Committees, there can be no doubt that this could only be done effectively with the Pharmaceutical Society as the central body. Mr. EDMUND WHITE, the president of the society, and other members of the Council, have shown by their untiring efforts that they are able and willing to overcome the problems which beset pharmacy.

Pharmaceutical Education.

No further steps appear to have been taken with regard to the introduction of a compulsory curriculum in connexion with the qualfying examination in pharmacy, and it is a question worth considering whether, after all, the best curriculum for the chemist is not a period of apprenticeship in a chemist's shop. There is hardly a pharmacy in the country where there is not now a sufficient amount of dispensing to allow of a pupil obtaining a good insight into the practical work of pharmacy, and under these circumstances few future candidates for the qualifying examination should be unprepared for the test in practical pharmacy and dispensing. A tendency to encourage boys who intend to adopt pharmacy as a career to pass the necessary preliminary examination before beginning their apprenticeship has become more pronounced, and it would perhaps be better for all concerned if this were made compulsory. The council of the Pharmaceutical Society no longer requires students to pass a preliminary examination in Latin, and this concession will no doubt greatly facilitate the passing of the preliminary examination before the apprenticeship is begun. In the earlier part of the year a series of post-graduate lectures on Microbiology and Pathological Chemistry in relation to the pharmacist was delivered in the Pharmaceutical Society's lecture theatre by Professor R. T. HEWLETT, of King's College, and it is not altogether improbable that when the syllabus of the major examination is overhauled the subject of pharmaceutical bacteriology may be introduced.

The Proprietary Medicines Inquiry.

The Select Committee on Proprietary Medicines resumed its inquiry in January, and subsequently held many sittings for the examination of witnesses. Representatives of proprietary medicine interests, analytical chemists, and others appeared before the Committee and produced in the aggregate a mass of evidence which will take a very considerable time to examine. An interesting witness was the president of the Pharmaceutical Society, who addressed himself mainly to questions arising out of the law concerning the sale of poisons. In some districts it has been the experience of chemists that the demand for proprietary medicines has decreased by reason of the fact that a large portion of the population is now supplied with medical advice and medicines by panel doctors and chemists respectively, but until the revenue returns showing the amount paid in medicine stamp duty for a full year during which the Insurance Act has been in operation are available, the extent to which the sale of proprietary medicines has diminished cannot be properly estimated.

The Sale of Poisons and Other Matters.

In March the Privy Council signified its approval of a resolution of the Pharmaceutical Society declaring certain hypnotic drugs, including veronal, to be poisons in the second part of the schedule to the Poisons and Pharmacy Act of 1908. In May a Privy Council Order came into force by which all liquid preparations sold as carbolic, or carbolic acid, or carbolic substitutes, or carbolic disinfectants containing not more than 3 per cent. of phenols were required to be sold by retail in bottles distinguishable by touch from ordinary bottles, the containers to be labelled "Poisonous—not to be taken," and with the name and address of the seller. In connexion with the administration of the penal clauses of the Pharmacy Acts the Pharmaceutical Society instituted proceedings in a large number of cases, but there appear to have been no cases before the courts presenting unusual features. It should be mentioned, however, that the Council recently prosecuted a Birmingham firm for selling snuff containing cocaine and omitting to observe the conditions concerning the sale of poisons. An unqualified person was charged at the instance of the Pharmaceutical Society with causing a false entry to be made in the register of chemists and druggists, and was convicted and fined £50; this appears to have been the first case of personation of this kind in which it has been the duty of the Pharmaceutical Society to take legal proceedings. In May the Departmental Committee on Jury

Service issued a report which contained the recommendation that chemists and druggists should be exempted from jury service; at present only pharmaceutical chemists are exempt, and it is hoped that in due course the Committee's recommendation will be embodied in an Act of Parliament. In August a Bill was introduced in the House of Lords by Lord LAMINGTON, the object of which was to prevent medical prescriptions which contained scheduled poisons from being used as a means of obtaining an undue quantity of the medicine prescribed. It provided that where the medicine prescribed by a medical practitioner contained a scheduled poison the prescription should not be dispensed more than once unless the medical attendant directed that it should be repeated. No progress was made with this measure, and it is doubtful whether it will receive enthusiastic support if it is reintroduced. The principle underlying the measure is no doubt sound, but it is questionable whether the proposed manner of applying it is the most expedient.

GENERAL MEDICAL COUNCIL.

The summer session of the General Medical Council lasted four days. An interesting report was received from the Education Committee on the standard of preliminary education in general knowledge. Recommendations from the committee were adopted by the Council with regard to the scope and character to be maintained in any preliminary examination in general education for which recognition is sought as qualifying for admission to the Students Register. The winter session also lasted four days and was presided over by Mr. C. S. TOMES, one of the Crown Representatives, in the unavoidable absence of Sir DONALD MACALISTER, who was, unfortunately, not well enough to be present. We note the way in which the business is disposed of in the minimum of time—viz., four days, because short sessions mean an enormous saving of expense. But we would remind our readers that these do not mean less work; they imply that the delegation of great quantities of work to good and energetic subcommittees is regularly bearing fruit. Among the most important business of this session may be mentioned certain cases of advertisement of medical men in the interests of Approved Societies, medical aid associations, and other institutions. The evidence before the National Health Insurance Act Committee that abuses of this sort were going on was abundant. It was considered *in camerâ*, but letters from the Registrar to a practitioner and to the secretary of a medical aid association pointing out the gravity of such irregularities were read in public. Mr. VERRALL pointed out that the transference of panel patients in bulk from one list to another conduced to the evil, and the Council unanimously resolved to call the attention of the National Insurance Commissioners to the necessity for preventing this practice.

The financial position of the Council is just now satisfactory, a surplus being announced for the last completed year (1912) of £1105 being largely accounted for by the reduction of over £900 in expenditure. The zeal of Mr. NORMAN KING, Registrar of the Council, in bringing about economies has contributed to the satisfactory position in which the Council now finds itself. It must be remembered that the income of the Council depends upon the number of medical men who pay for registration, and that the outgoings of the Council are to a great extent regulated by the length of the sessions. If in any year the Council, receiving a smaller sum than usual, is by unavoidable circumstances driven to hold long or additional sessions, the surplus would inevitably be replaced by a deficiency.

BRITISH MEDICAL ASSOCIATION.

The British Medical Association has had an anxious year. The responsibilities and expenses have been much aggravated by its great services in regard to the National Insurance Act, and at the annual meeting held this year at Brighton proposals were ventilated to raise the annual subscription and to form a fighting and insurance fund of voluntary members. The meeting was well attended in face of the fact that the International Medical Congress was due only a few days later, and the Representative Body of the Association duly approved the recommendation of the Council to raise the annual subscription of the Association to £2 2*s*. and to form a great fund for organisation and defence purposes.

A Special Representative meeting was held in London at the beginning of December, when it was agreed, by the necessary majority, to raise the annual subscription to £2 2*s*.; but consideration of the scheme to raise a fund from 10,000 members at an annual subscription of £4 4*s*. for the development of the organisation of the profession was postponed until next July.

MEDICAL PRACTICE UNDER THE NATIONAL INSURANCE ACT.

Our readers have been kept informed of the working of the National Insurance Act throughout the year, and have probably reached the conclusion which we have reached, that nothing like finality in the arrangements for the administration of medical benefit can be expected for a long time. A general movement on the part of a large group of medical men to alter the legal basis upon which the administration of medical benefits is now founded came into existence at the close of the year. The broad expectation of this group is that a strong combination of practitioners, resolved in no circumstances to serve on the panels, may result in the repeal of the contract system, and the distribution of the funds to the insured persons with discretion as to the way the money is spent. Of course, the possibility that such a movement, if successful, would lead directly to a State medical service has been fully recognised by the protagonists. Associations have also been formed to protect the interests of panel practitioners and to promote the formation of a State medical service. The medical profession as a whole is not yet reconciled either to the principles or to the working of the measure. There is no unanimity of this kind to record, even if active opposition to the Act has much decreased. It is perfectly true that the incomes of many medical men have been improved by position upon the panels, but at the same time the Regulations under which medical benefit is administered, despite various recent modifications, are not satisfactory, and the latest Regulations have come in for a good deal of legitimate criticism in our columns and elsewhere. The attitude of the Commissioners towards those who have approached them with representations that the Regulations

read oppressively in various directions has been studiously conciliatory.

That our readers might follow the working of the Act we sent a Special Commissioner to report from week to week upon the points of particular interest in different centres.

Southampton, Kent, and Reading.

In commencing his investigations our Special Commissioner first went to Southampton, a town with which he was familiar, having described on previous occasions how the medical practitioners residing there had united to provide medical aid for those who could not pay the minimum fees. The Provident Medical Association thus formed was converted into the Public Medical Service and now deals mainly with the dependents on the insured. With regard to insured patients great difference of opinion existed among the medical men whether the Act was right or wrong. It was held by some that the regularity of payment from all, whether ill or well, would give a better result. The fees obtained from private patients whose incomes exceeded £100 a year, and were under the income-tax limit, would be lost, but poorer patients would not be treated for next tonothing. In the richer parts of the town practitioners held the opposite opinion.

In Kent, at Gillingham notably, the greatest animosity against the Act was manifested. The possibility that it would encourage the "sweating" of medical men engaged at fixed salaries by institutions that had provided medical aid before the passing of the Act was early seen. Of 800 practitioners in Kent only some 50 joined the panel, and the feeling at Gillingham between the "panelites" and the "anti-panelites" was so strong as to interfere with the amenities of life. Some sections of the public also joined in the outcry against the Act, and when ill refused to consult their panel doctor. This feeling was accentuated by the fact that the panel doctor who enjoyed the highest reputation resigned his position on the panel after giving the system only ten days' trial.

At Reading the medical profession, being well organised, succeeded in carrying several important points. There existed an old-fashioned dispensary with more than 16,000 members out of a population of 72,000. When the Act came into force, to avoid fighting this institution the local practitioners constituted themselves into the Borough of Reading Medical Society, Limited, and bought up the Reading Dispensary and all its appurtenances. At the same time, as the object was to regulate medical practice and not to make profits, the shares bear no dividend. The Reading Dispensary provides medical attendance for the non-assured within a well-established wage limit and on a sliding scale of small subscriptions, according to the position of the subscriber. Thus early in the investigation it became evident that the position of the dependents on the insured was a matter of almost as much concern as that of the insured themselves. The Reading Insurance Committee was one of the few rare and exceptional committees who agreed to establish a wage limit, which, however, it fixed at £2 10*s.* a week, a figure too high to be of practical use beyond constituting an acknowledgment of the principle that under the Act Insurance Committees can impose a wage limit for the receipt of medical benefit through the official channel. The wage limit was abandoned.

Carlisle.—Scotland.

Travelling to Scotland, but stopping on the frontier at Carlisle, our Commissioner had his first experience of practitioners and conditions favouring the Act. Certainly it was only a minority who favoured the Act, but they persuaded the others to accept its conditions. Those who held large club practices found that the 7*s.* under the Act, instead of from 2*s.* 6*d.* to 4*s.* which they used to receive from the clubs, greatly increased their incomes, even if the work was harder. Others, while acknowledging the financial advantage, felt that their work was not in keeping with the dignity of the profession or likely to promote the best interests of medical science.

Dumfries was the next centre visited, and there our Commissioner first came upon the allurements of sick pay. Thus a labourer belonging to two Friendly Societies that allowed 9*s.* a week sick pay, making when added to the 10*s.* under the Insurance Act a total of 28*s.* a week, was receiving when ill a good deal more than, as a labourer even when in full work, he could hope to earn. Such conditions constitute a strong temptation to malingering. It was at Dumfries also that the effect of the Act in reducing the sale of quack medicines was first demonstrated to him. In Scotland insured persons soon discovered that they could get medicine for nothing, with a much better chance of its proving to be the sort of medicine they really needed than they ever had when nostrum buying.

Nor was there much opposition shown to the Act at Glasgow. It was felt that the medical practitioner was in a better position under the Insurance Committees than under the lay committees, composed for the most part of workmen who were his employers when he worked for a club or a Friendly Society. But financial and scientific interests do not harmonise. The poorest class of practice pays best in Glasgow, it appeared, for here the least attention need be given to each patient; in fact, the profit of contract work depends on the quantity of patients seen rather than on the quality of the work done. From Glasgow our Commissioner visited the neighbouring mining centre of Bothwell, the metal working centre of Motherwell, and the agricultural centre of Milngavie. One of the unexpected results of the Act was discovered in connexion with mines and great iron-works. Here the workmen were attended by what was known as the "works' doctor," sometimes engaged by the employers, sometimes elected by the working men, but always enjoying a monopoly. This privilege is now destroyed, and the "works' doctors" have become panel doctors with the same chance as all the other neighbouring practitioners. Consequently the Irish and Roman Catholic workmen were free to select as their medical attendants such men of their own country and faith as might be on the panels. It results that at Glasgow, at Motherwell, and many other industrial centres throughout the country, where Irish labour has been attracted, the Roman Catholic doctors have suddenly received a great increase of patients. It became clear from experience here that in industrial centres anxiety prevails as to what will be done for the dependents of the insured; and where the workmen are organised in strong trade unions there the medical practitioners also feel they should be banded together in a similar fighting organisation with a substantial strike fund to fall back upon.

From Glasgow our Commissioner went to Edinburgh, where he found the Scotch Commissioners

labouring to make the Act efficacious, while a large section of the profession objected to the measure as injuring the science of medicine, and as causing a split of the profession into two sections, those who served on the panel and those who preserved their independence. Nowhere in any of the places reported upon in THE LANCET was the dividing line so sharply drawn as at Edinburgh. Further, in Edinburgh it was emphatically declared that if a limit was needed in regard to insured persons' wages it should also be imposed on medical men, who should not be allowed to have an unlimited number of insured persons on their list. As a radical solution to all these problems, in the far north, Dr. MATTHEW HAY, medical officer of health of Aberdeen, described his elaborate scheme for a State medical service. There was also at Aberdeen some interesting evidence as to the decline in the sale of patent medicines and self-drugging since the Act came into force.

Lancashire, Cheshire, and Yorkshire.

Our Commissioner next made a tour in Lancashire and Yorkshire, commencing with Blackpool. In Blackpool the very exceptional conditions of medical practice among 64,000 inhabitants who receive some three million visitors in the course of the year were the subject of interesting comment. Most of the sickness depends on holiday-making and it generally prevails from 10 at night to 3 in the morning, when the effects of self-indulgence become most evident. The steady working of the Act under such unsteady circumstances was not to be expected, and no one at Blackpool felt the need for any such legislation.

In Liverpool the Act appeared to be very unpopular in some districts. Several panel doctors are receiving quite large incomes for doing little or nothing. The insured persons on their lists prefer not to consult their panel doctors, and pay fees to independent doctors. On the other hand, among the poorer sections of the community, notably the great crowd of casual and dock labourers, the Act is doing a great deal of good. This is more particularly the case now that the difficulties due to the casual nature of the work have in a great measure been met by the establishment of the admirable Dockers' Clearing House which our Commissioner described.

At Manchester and Salford the working of the pooling system was closely examined and described. Then Altrincham, where a Parliamentary election is supposed to have been greatly influenced by the Act, was visited, and some of the conditions of semi-rural practice came under observation. The feeling against the Act may be judged by the fact that in the county of Cheshire out of 460 medical practitioners only eight went on the panel previous to the general surrender.

The great show of resistance put up at Bradford was described, but our Commissioner found that the Act, being accepted, is working well in some of the worst districts. But at Bradford so many women workers contrived to get on the sick pay list during the early part of the year that it was flippantly suggested they were "spring cleaning." At Leeds, where the profession is not strongly organised, the Act was readily accepted. Unpopular in the residential districts, it is considered a boon in the vast areas inhabited almost exclusively by the working class, and here the former club doctors are reaping a rich harvest. But there is abuse in so far as several panel doctors have too many insured persons on their lists.

At Hull details were obtained as to the conflict between the Friendly Societies and the commercial insurance companies, who both seek to work the Act. More was said in favour of the Friendly Societies than is generally heard. Here also there was some evidence as to what medical practitioners who are militant Socialists think of the Act. Among other interesting items, a practitioner who had succeeded in placing 800 picked lives on his list had so little to do that the average receipt for each item was 3*s*. 6*d*., while another practitioner, attending to 1700 dockers, women workers, and a poor class of people, had so much to do that he only received 1*s*. 6*d*. per item, though, of course, in both cases the insured persons paid the same amount.

Newcastle-on-Tyne.

Going further north our Commissioner reached Newcastle-on-Tyne, where in days not long gone by a well-organised profession had won many hard-fought battles. At Newcastle there are some excellent illustrations that a wage limit is really needed. This great fact stands forth that, though there are not many insured persons whose income is above £2 a week, these are apt to live close together in the same district, and the local practitioner is severely hit. Formerly they all paid fees, and to-day they fear a more perfunctory treatment involved in contract practice. Thus in the west end of Newcastle not more than five visits can be made in the hour, while in the Heaton district it is possible to get through 20 visits in the hour. Therefore, the practitioner at Heaton finds panel work pays him well, and the west end practitioners find that it involves them in such a loss that several have resigned and left the panel.

The Midlands.

Our Commissioner next proceeded to the Midland Counties and dealt with the problem arising from the excessive amount of female labour in such towns as Nottingham and Derby. Then there was the competition against panel doctors and panel chemists by institutes that provided medical aid before the Act and have so many members as to cause a very serious grievance at Chesterfield and at Derby. Later on, in South Wales, the same trouble was also examined on the spot. The women workers, being for the most part in receipt of wages that do not often exceed 10*s*. a week, are in a very low state of health and need far more medical attendance and are more frequently on the sick list, claiming sick pay, than the average male population. This is bringing light into dark places where reform is urgently needed, but it is imposing more medical work and heavier financial burdens than were anticipated by the framers of the Act.

The authorities in the great town of Birmingham believe that they are working the Act very successfully. But this does not prevent individual practitioners from arguing that in some instances the poor obtained better care under the old club system. The club doctor only treated minor illnesses and there were institutions and hospitals for graver cases. Now the latter are attended, according to the methods of contract practice, by panel doctors, and sometimes fare worse.

South-West Counties and South Wales.

From the Midlands our Commissioner went south-west, visiting Exeter and Bristol. The county of Devon, though the largest area in England, has but a small population, with vast rural districts where there is but 0·23 inhabitant per acre. The question of mileage, therefore, becomes very important. Thus it happened in

one instance that a panel doctor had to pay a patient who lived eight miles away 40 visits. Counting the return journeys, it was necessary to ride—the roads not being good enough for a conveyance—no less than 640 miles to attend to this one case. In the town of Exeter we had the unusual spectacle of the Friendly Societies and the medical profession working hand-in-hand to improve the Act.

Finally, several places in South Wales and Monmouthshire were visited, and a full description was given of the way in which Subsection 3 of Section 15 of the Act has been so stretched as to defeat Subsection 4 of the same section by allowing institutions giving medical aid to be created after the Act. It remains to be seen whether, following the example of the Swansea Hospital, this will be rendered impossible by the staffs of hospitals refusing to have anything to do with the patients as well as the medical officers of such institutions. There are places in Wales where the panel doctors have lost two-thirds of their incomes by the creation of these institutions after the passing of the Act.

Altogether our Commissioner has written 33 articles dealing with 31 different towns in industrial or agricultural centres. For this purpose he had to travel and take up quarters in 26 towns, and the value of his first-hand investigations in our view lies in the fact that in every case something new was found, some feature, often a very important feature, was discovered in the working of the Acts which demanded to be dealt with. The investigations will be continued next year.

HOSPITAL FUNDS.

Recent legislation has greatly perturbed voluntary contributions to hospital charities, and the three great Funds which have done so much to foster and coördinate the voluntary system have alike felt the untoward influence of hastily conceived economic experiments.

Metropolitan Hospital Sunday Fund.

Notwithstanding the strenuous efforts of the ex-Lord Mayor, Sir DAVID BURNETT, president and treasurer, on behalf of the Metropolitan Hospital Sunday Fund, there has been a decrease in the total collection compared with last year of £2981, the amount for 1913 being £64,992. In the various places of worship £28,434 were collected, or £7432 less than in 1912. Christ Church, Lancaster Gate, headed the list of contributing congregations with £839. The donations and legacies, with interest on investments, amounted to £36,558. Awards were made to 155 hospitals, 12 institutions, 57 dispensaries, and 33 nursing associations.

King Edward's Hospital Fund for London.

A satisfactory feature in connexion with the history of this Fund for the year was the announcement at the meeting of governors and the general council held at St. James's Palace on Dec. 12th that the difference between the Fund and St. George's Hospital had been settled, and that a grant of £3000 had been recommended. As the Duke of TECK, who presided, pointed out, it had never been suggested that there was any want of good faith on the part of the hospital authorities, the difficulty arising solely from the fact that the Fund was bound by a special trust in the matter of the financial relations of hospitals and medical schools. Annual subscriptions show a slight increase and donations a decrease, the amount received, after payment of expenses, being £150,692. There has been an increase in the income from investments by £2000, and £170,000 are on deposit at the bankers. The amount available for distribution (£157,500) is rather larger than that available last year, and there has been no necessity to draw upon reserves as was done in 1912. Under the will of the late Sir JULIUS WERNHER a sum of about £465,000, which it is proposed to use as a permanent investment, is due to the Fund. The approximate total collection of the League of Mercy amounts for the year to £17,227. The total grant to hospitals will amount to £151,000, to consumption sanatoriums £3975, and to convalescent homes £2525.

Hospital Saturday Fund.

Up to about the middle of December the Hospital Saturday Fund had received more than £19,500 in contributions, showing a decrease of over £4000 when compared with the corresponding period of last year.

HONOURS TO MEDICAL MEN.

The year that is closing has not seen a very long Honours list for medical men, but the following members of our profession have received public recognition for their services to the Sovereign and to the Empire. The military and naval honours have been elsewhere noted.

The New Year Honours.

Four new medical knights were created, these being Sir FRANCIS DARWIN, F.R.S., the distinguished botanist; Sir ROBERT WILLIAM PHILIP; Sir DAVID HARDIE, of the Queensland Central Board of Health; and Sir GEORGE TURNER, formerly medical officer of health of the Transvaal. In the Order of the Bath Inspector-General Sir DUNCAN HILSTON, R.N., was promoted from C.B. to K.C.B.; and in the Order of the Indian Empire Major WILLIAM GLEN LISTON, I.M.S., and Lieutenant-Colonel WALTER JAMES BUCHANAN, I.M.S., were made Companions. Major HENRY WILLIAM GRATTAN, R.A.M.C., Dr. JOHN ANDREW TURNER, Major ERNEST REINHOLD ROST, I.M.S., and Major ELLACOTT L. WARD, I.M.S., received the Kaisar-i-Hind Gold Medal.

The Birthday Honours.

On the occasion of the King's birthday Mr. WILLIAM ARBUTHNOT LANE received a baronetcy. Major EDWARD S. WORTHINGTON, M.V.O., R.A.M.C., had conferred upon him the honour of knighthood, as did also Lieutenant-Colonel JAMES REID ROBERTS, C.I.E., I.M.S., surgeon to the Viceroy of India. Sir ALEXANDER MACCORMICK, of Sydney, New South Wales; Sir THOMAS E. FLITCROFT; Sir ANDREW J. HORNE, a past President of the Royal College of Physicians of Ireland; Sir HERBERT SMALLEY; Sir ROBERT H. WOODS, a past President of the Royal College of Surgeons in Ireland; and Sir EDWARD A. SCHÄFER have also been knighted. In the Order of the Bath Surgeon-General Sir HENRY HAMILTON, C.B., I.M.S., was promoted to K.C.B., and Companionships were conferred upon Deputy Surgeon-General WILLIAM MAXWELL CRAIG, R.N.; Surgeon-General LOUIS EDWARD ANDERSON, Deputy Director of Medical Services in Ireland; and on Lieutenant-Colonel JOHN CRIMMIN, V.C., C.I.E., I.M.S. In the Order of St. Michael and St. George Dr. H. P. KEATINGE and Mr. A. H. SPURRIER received Companionships. In the Order of the Star of India Lieutenant-Colonel GERALD

GODFRAY GIFFARD, I.M.S., was made a Companion, and in the Order of the Indian Empire a similar honour was conferred upon Major ROBERT J. BLACKHAM, R.A.M.C. Colonel WILLIAM HENRY BULL, A.M.S. (T.F.), and Colonel JOHN ARNALLT JONES, A.M.S. (T.F.), were appointed Honorary Surgeons to His Majesty, and Colonel WILLIAM KINNEAR, A.M.S. (T.F.), and Colonel CHARLES PYE OLIVER, A.M.S. (T.F.), Honorary Physicians to His Majesty,

Foreign Orders.

The decoration of the Fourth Class of the Imperial Ottoman Order of the Medjidieh was given to Captain R. G. ANDERSON, R.A.M.C., and to Captain R. G. ARCHIBALD, R.A.M.C. Captain J. POWELL, R.A.M.C., received the Imperial Order of the Osmanieh (Fourth Class).

The Antarctic Medal.

The silver Polar medal with clasp inscribed "Antarctic, 1910–1913," was granted to Surgeon E. A. WILSON (deceased), and the clasp only (the recipients already possessing the Polar medal) to Surgeon G. M. LEVICK, R.N., and Surgeon E. L. ATKINSON, R.N., members of the British Antarctic Expedition, 1910–13. Surgeon LEVICK and Surgeon ATKINSON were also notified for special promotion.

OBITUARY.

We make no attempt to do more than recall to our readers the names of the more prominent medical men who have passed during the year from among us. Their names in most cases will recall their work to our readers.

In medicine, in addition to those whose deaths are elsewhere mentioned, we deplore the loss of Dr. WILLIAM HOWSHIP DICKINSON, Dr. GEORGE ALEXANDER GIBSON, Dr. WILLIAM CARTER, of Liverpool, Dr. ALFRED BAYNARD DUFFIN, Professor SAMSON GEMMELL, Dr. CHARLES LESTER LEONARD, of Philadelphia, and Dr. WILLIAM CARNEGIE BROWN.

In surgery we have lost Sir JONATHAN HUTCHINSON, Mr. ALFRED WILLETT, Mr. WALTER WHITEHEAD, Mr. ANDREW CLARK, Dr. JUST MARIE MARCELLIN LUCAS-CHAMPIONNIÈRE, Professor CHARLES MCBURNEY, of New York, Mr. SYDNEY JONES, Sir THOMAS CHAVASSE, Professor JORDAN LLOYD, and Mr. EDWARD WILKINSON ROUGHTON.

Among obstetricians and gynæcologists our death roll includes Dr. ALFRED LEWIS GALABIN, Mr. JAMES HENRY TARGETT, and Dr. CLEMENT GODSON.

Anatomy, physiology, and pathology have to deplore the loss of Professor FRANCIS GOTCH, Professor EDWIN ELLEN GOLDMANN, of Freiburg, Professor EDWIN KLEBS, Professor PETER REDFERN, Dr. LEONARD NOON, and Professor NATHANIEL HENRY ALCOCK.

Among those whose career was devoted to public health are Dr. JOHN FREDERICK JOSEPH SYKES, Dr. HENRY FRANKLIN PARSONS, and Dr. RICHARD DEANE SWEETING, senior medical inspector of the Local Government Board.

Finally, some who for special reasons call for mention are Lord ILKESTON and Sir JOHN BATTY TUKE, who, though primarily distinguished, the one as a physician, the other as an alienist, later made their reputations in the political world, and Mr. R. B. ETHERINGTON-SMITH.

We should also mention Dr. WILLIAM LIVESAY, who took part in Arctic exploration; Dr. EDWARD ADRIAN WILSON, of the Scott Expedition; Dr. JOHN SHAW BILLINGS, of New York, the renowned medical librarian; Dr. WILLIAM HENRY LANGLEY, principal medical officer of Southern Nigeria; and Professor ROBERT KUTNER, of Berlin, whose name is associated with the systematisation of post-graduate study, and who founded and edited the *Zeitschrift für Aerztliche Fortbildung.*

Annotations.

"Ne quid nimis."

THE SITE OF THE UNIVERSITY OF LONDON.

As we recorded last week, during an all-night sitting the London County Council on Dec. 16th discussed the question of the site of the University of London. The Education Committee recommended approval of Somerset House for the purpose, but the Improvements Committee urged the erection of buildings on the south side of the Thames, adjoining the County Hall now being erected at the south-east corner of Westminster Bridge. This proposal, however, was negatived by 28 votes to 26, and the Council agreed to join with the Senate of the University in asking the Government to grant the use of Somerset House, and to be responsible for the cost of housing the University, as heretofore. The Departmental Committee of the Board of Education will therefore have to consider how far the granting of the use of Somerset House to the University will comply with the recommendation of the Royal Commission that a University quarter is needed.

THYROID SECRETION AND ANTITOXIN.

THE communication from Mr. Rupert Farrant, which appears on another page, contains further observations on the subject of the relationship between the thyroid gland and the formation of diphtherial antitoxin. In a former paper read before the Royal Society of Medicine Mr. Farrant put forward the suggestion that the hyperplasia of the thyroid found to exist in horses immunised with diphtherial toxin was a sign of active secretion from the gland, and stated that this secretion could be recognised in the blood of the animals, both in the form of increased iodine content, and also by the toxic effects induced in rabbits by injection of antitoxic serum, these animals dying under conditions identical with those seen after injection of thyroid preparations. In the present paper this latter series of phenomena is confirmed by further observations, and the presence in antitoxic serum of a substance acting like thyro-iodine is established. There is, however, no definite evidence that the iodine content of the serum increases in proportion to the number of units of antitoxin contained in it. The behaviour of the thyroid gland in horses used for preparation of diphtherial antitoxin is remarkable. In them the first injections of toxin appear to induce hyperplasia of the glandular epithelium, but as their antitoxic immunity increases with subsequent injections the disturbance in the thyroid subsides, the degree of change found microscopically in the gland being inversely proportional to the antitoxic power of the serum. Mr. Farrant infers that the gland gains increasing protection from the antitoxin present in the blood, but it might equally be suggested that tolerance is produced, the gland gradually resuming its normal state. However that may be, the

subsidence of disturbance as the formation of antitoxin advances negatives the idea that the secretion of the thyroid gland takes any part in the production of the antibody, and this independence is confirmed by the absence of any trace of antitoxic power in the gland itself. No efficacy in neutralising toxin was found to be possessed by the substance of the gland or by its colloid secretion, whether they were administered by the mouth or hypodermically, while the serum of an animal fed on the substance of the gland was similarly devoid of antitoxic influence. It appears, then, that diphtherial toxin stimulates the thyroid to increased activity, and that the secretion thus formed in excess may be recognisable in commercial antitoxic serum, but that this secretion does not take any part in the formation of antitoxin either as a chemical constituent or as an adjuvant in its production.

METROPOLITAN ASYLUMS BOARD: INSTITUTIONAL TREATMENT OF TUBERCULOSIS IN LONDON.

AN elaborate report on the subject of the treatment of tuberculosis in London and the share in that work of the Metropolitan Asylums Board was presented to the Board on Dec. 13th by the Law and Parliamentary Committee. The report dealt with the history of the question in some detail, mentioning the exclusion of the Board (on the ground of being a Poor-law authority) from taking part in the administration of the National Insurance Act of 1911, its subsequent inclusion in the Amending Act, 1913, and the legalisation, under Section 3 of the Public Health (Prevention and Treatment of Disease) Act, 1913, providing that the Board, under agreement with other authorities, should have care of uninsured tuberculous persons. The committee accepted the view of the Local Government Board, the London County Council, and the London Insurance Committee that the resources of the Board should be utilised as far as possible in making provision for insured and uninsured tuberculous persons, and pointed out that the accommodation provided by the Board up to the present had alone enabled effect to be given in the metropolis to the sanatorium provisions of the Insurance Act in anything like a reasonable time. The report foreshadowed the permanent accommodation required as of the following character: (1) Sanatoriums for early cases of pulmonary tuberculosis in both sexes; (2) sanatoriums for children, affording educational facilities; (3) hospitals for rest cases and observation purposes, and for chronic, incurable, and advanced cases. The Board is well placed in regard to provision for tuberculous children, and provision of hospital accommodation for advanced adult cases need not offer much difficulty, but it will be essential to provide one or two new sanatoriums on entirely modern lines for the treatment of early cases of pulmonary tuberculosis in adults, a necessity which was fully recognised by the Law and Parliamentary Committee. The Board passed a series of resolutions expressing willingness to enter into agreements with the London County Council and the London Insurance Committee for the provision of residential institutional accommodation for insured persons and their dependents and for uninsured persons. It was agreed to find accommodation in existing institutions where possible, to provide one or two new sanatoriums for early adult cases, and to refer to a committee the desirability of purchasing the Mount Vernon Hospital. The Local Government Board will also be asked to consider the possibility of some relief of Poor-law institutions following upon the working of the National Insurance Act, so that rearrangements and amalgamations might set free accommodation for tuberculous persons.

ROYAL COMMISSION ON VENEREAL DISEASES.

AT the seventh meeting of the Royal Commission on Venereal Diseases, held on Dec. 8th, evidence was given by Dr. F. W. Mott, F.R.S., pathologist to the London County Council Asylums and a member of the Commission.

Dr. Mott dealt first with dementia paralytica, or general paralysis of the insane. He indicated the grounds on which it is held that syphilis is the essential cause of this disease, that without syphilis there would be no general paralysis. Facts relating to general paralysis had therefore an important bearing on the Commission's inquiry. Dr. Mott gave various statistics respecting cases of this disease dealt with in the County Council Asylums. From a comparison of the figures for the last 15 years, during which the population of London has remained practically stationary, he came to the conclusion that the admissions of cases of general paralysis were not diminishing, though he could not say that there was an increase. The figures of annual admissions showed that 8 per cent. of the total admissions from all causes and 15½ per cent. of the male admissions were general paralytics. The male cases of general paralysis of the insane considerably outnumbered the female, the ratio between them being rather more than 5 to 1. Tables of the numbers of cases of the disease from different districts of London indicated a higher incidence among males in the West-end than in the East-end, while among females the higher incidence occurred in the East-end.

Dr. Mott also gave the results of some researches he had carried out regarding the existence of the effects of gonorrhœa in women dying from general paralysis of the insane. Obvious signs of gonorrhœal infection were found in 50 per cent. of these cases. Other investigations which he had carried out dealing with arterial disease in general paralytics showed that among persons who have had syphilis disease of the arteries occurs more frequently and at an earlier age than in the general population.

On the subject of infant mortality Dr. Mott stated that if the causes could be satisfactorily ascertained the statistics of infant mortality would give important indications of the prevalence of syphilis in the country. He submitted diagnoses of family histories illustrating the effects of parental syphilis in producing premature births, stillbirths, children dying in early infancy, and afterwards living children suffering in later life from the effects of congenital syphilis in some form or other. Among the serious effects were blindness, deafness, stunted growth, paralysis, dementia paralytica, imbecility, fits, and general debility. The histories of 34 syphilitic mothers gave 175 conceptions resulting in 104 premature births, stillbirths, and deaths in early infancy, 41 diseased in some serious form or other, and only 30 apparently healthy or doubtful. 2 per cent. of all cases of general paralysis of the insane were juvenile cases due to congenital syphilis. The percentage would be very much higher but for the fact that the majority of children whose brains became affected die in early life or are born dead. Dr. Mott laid great stress on the desirability of doing a Wassermann test for every newly-born infant when the parent has syphilis or is suspected of syphilis, as it would then be possible to deal with latent disease in the child.

With regard to the Wassermann test Dr. Mott described the work which had been done in the pathological laboratories of the London County Asylums, and he explained the value of the test in enabling the practitioner to forestall symptoms by treatment. He said that the essential point in the treatment of syphilis was to detect the organism at the earliest possible time and to begin treatment immediately. He advocated very strongly the provision of public laboratories where Wassermann tests and bacteriological examinations could

be carried out. It was also of the utmost importance that satisfactory education should be provided for medical students, so that they should thoroughly understand syphilis and how to diagnose it in its early stages, so that all delay in dealing with the disease might be avoided.

At the eighth meeting of the Royal Commission on Venereal Diseases evidence was given by Sir William Thompson, Registrar-General for Ireland. He said that as a cause of deaths venereal diseases played relatively a small part in Ireland. The death-rate from syphilis and allied diseases was 0·78 per 10,000 of the population, whereas the figures for tuberculosis at the head of the list were 21·52 per 10,000. Compared with previous years the deaths from syphilis and general paralysis of the insane appear to show a tendency to increase, but Sir William Thompson thought that much of the increase was more apparent than real, and was due to the more careful recording of deaths. The greater part of the deaths from venereal diseases occurred in the two cities Dublin and Belfast. In Dublin the figures were abnormally high, the death-rates from syphilis and general paralysis of the insane being about twice those for London. On the whole the incidence of venereal diseases in Ireland was very much lower than in the rest of the United Kingdom; the syphilis death-rate was only that of England and Wales, while with regard to infant mortality the nnmber of deaths due to syphilis per 1000 births in the three kingdoms were: England and Wales, 1·29; Scotland, 1·4; and Ireland, 0·59.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8408 births and 4952 deaths were registered during the week ended Saturday, Dec. 13th. The annual rate of mortality in these towns, which had been 13·4, 14·1, and 13·2 per 1000 in the three preceding weeks, rose to 14·5 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual death-rate in these towns averaged 13·7, against a corresponding rate of 13·6 per 1000 in London during the same period. Among the several towns the death-rate ranged from 3·6 in Wimbledon, 4·8 in Newport (Mon.), 5·2 in Enfield, 7·9 in Aberdare, and 8·3 in Hornsey, to 20·8 in South Shields, 21·0 in Great Yarmouth, 21·4 in Swansea, 24·1 in Middlesbrough, and 26·3 in Dudley.

The 4952 deaths from all causes were 448 in excess of the number in the previous week, and included 324 which were referred to the principal epidemic diseases, against numbers steadily declining from 925 to 269 in the nine preceding weeks. Of these 324 deaths, 94 resulted from infantile diarrhœal diseases, 70 from diphtheria, 57 from whooping-cough, 54 from measles, 26 from enteric fever, and 23 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases in the week under notice was equal to 0·9, against 1·0 and 0·8 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 149, 152, and 101 in the three preceding weeks, further declined to 94; of this number 34 were recorded in London, 4 in Portsmouth, 4 in Bristol, and 3 each in Stoke-on-Trent, Oldham, Middlesbrough, and Newcastle-on-Tyne. The deaths referred to diphtheria, which had been 76, 65, and 45 in the three preceding weeks, rose to 70 during the week, and included 18 in London and its suburban districts, 9 in Birmingham, and 8 in Manchester. The fatal cases of whooping-cough, which had been 33, 39, and 32 in the three preceding weeks, rose to 57; 14 deaths were registered in London, 8 in Birmingham, and 6 in Liverpool. The deaths attributed to measles, which had been 50, 39, and 40 in the three preceding weeks, rose to 54 in the week under notice, and included 11 in Burnley, 7 in Sheffield, 6 in London, and 3 each in Leicester, Barnsley, and Middlesbrough. The deaths referred to enteric fever, which had been 21, 18, and 14 in the three preceding weeks, rose to 26, which was the highest number of deaths from this disease recorded in any week of the current year; of this number 3 occurred in London, 3 in Newcastle-on-Tyne, 2 in Nottingham, and 2 in Rhondda. The fatal cases of scarlet fever, which had been 32, 35, and 37 in the three preceding weeks, declined to 23, and included 5 in London, 3 in Liverpool, and 2 each in Birmingham, Manchester, Salford, and South Shields.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had steadily increased from 2112 to 4143 in the 14 preceding weeks, slightly declined to 4137 on Dec. 13th; 552 new cases were admitted during the week, against 558, 618, and 524 in the three preceding weeks. These hospitals also contained on Dec. 13th 1160 cases of diphtheria, 169 of whooping-cough, 61 of enteric fever, and 54 of measles, but not one of small-pox. The 1231 deaths from all causes in London were 129 in excess of the number in the previous week, and were equal to an annual death-rate of 14·2 per 1000. The deaths referred to diseases of the respiratory system, which had been 214, 261, and 227 in the three preceding weeks, rose to 291, but were 54 below the number registered in the corresponding week of last year.

Of the 4952 deaths from all causes in the 96 towns, 188 were attributed to different forms of violence, and 432 were the subject of coroners' inquests. The causes of 33, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Salford, and in 55 other smaller towns. Of the 33 uncertified causes of death, 5 were registered in Liverpool, 4 in Birmingham, 3 in Coventry, 3 in St. Helens, and 2 in Warrington.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1107 births and 734 deaths were registered during the week ended Saturday, Dec. 13th. The annual rate of mortality in these towns, which had been 15·8, 17·0, and 15·6 per 1000 in the three preceding weeks, rose to 17·0 per 1000 in the week under notice. During the first eleven weeks of the current quarter the mean annual death-rate in these towns averaged 15·2, against a corresponding rate of 13·7 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate ranged from 9·2 in Ayr, 11·0 in Clydebank, and 12·0 in Kilmarnock, to 20·2 in Aberdeen, 22·3 in Perth, and 25·3 in Coatbridge.

The 734 deaths from all causes were 57 in excess of the number in the previous week, and included 86 which were referred to the principal epidemic diseases, against 75 and 83 in the two preceding weeks. Of these 86 deaths, 36 resulted from measles, 17 from diphtheria, 13 from infantile diarrhœal diseases, 12 from scarlet fever, 6 from whooping-cough, and 2 from enteric fever, but not one from small-pox. These 86 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·0, against 0·9 per 1000 in the 96 large English towns. The deaths attributed to measles, which had been 33, 35, and 40 in the three preceding weeks, declined to 36 in the week under notice; of this number 16 occurred in Glasgow, 5 in Motherwell, 4 in Edinburgh, and 2 each in Greenock, Coatbridge, Kirkcaldy, and Clydebank. The deaths referred to diphtheria, which had been 10, 14, and 12 in the three preceding weeks, rose to 17, and comprised 7 in Aberdeen, 6 in Glasgow, and 4 in Edinburgh. The fatal cases of diarrhœa and enteritis among infants under 2 years, which had been 14, 8, and 14 in the three preceding weeks, were 13 in the week mentioned, and included 5 in Glasgow, 3 in Aberdeen, and 2 in Dundee. The deaths attributed to scarlet fever, which had been 6, 11, and 8 in the three preceding weeks, rose to 12, and included 6 in Glasgow and 3 in Edinburgh. The 6 deaths referred to whooping-cough were 2 in excess of the average in the earlier weeks of the quarter, and comprised 4 in Glasgow, 1 in Paisley, and 1 in Coatbridge. The 2 fatal cases of enteric fever were recorded in Glasgow and Aberdeen respectively.

The deaths referred to diseases of the respiratory system, which had been 119, 129, and 123 in the three preceding weeks, rose to 157 in the week under notice; 30 deaths were attributed to various forms of violence, against 26 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,199,180 persons at the middle of this year, 589 births and 407 deaths were registered during the week ended Saturday, Dec. 13th. The annual rate of mortality in these towns, which had been 16·4, 16·6, and 16·0 per 1000 in the three preceding weeks, rose to 17·7 per 1000 in the week under notice. During the first 11 weeks of the current quarter the mean annual death-rate in these Irish towns averaged 17·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·7, while in the 16 Scotch towns it was equal to 15·2 per 1000. The annual death-rate recorded in the week under review was equal to 17·6 in Dublin (against 14·2 in London and 18·5 in Glasgow), 18·0 in Belfast, 21·1 in Cork, 8·9 in Londonderry, 12·2 in Limerick, and 9·5 in Waterford, while in the 21 smaller towns the mean death-rate reached 19·7 per 1000.

The 407 deaths from all causes were 40 in excess of the number in the previous week, and included 36 which were referred to the principal epidemic diseases, against 30 and 36

in the two preceding weeks. Of these 36 deaths, 8 resulted from scarlet fever, 8 from diphtheria, 6 from whooping-cough, 6 from infantile diarrhœal diseases, 6 from enteric fever, and 2 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·6 per 1000; in the 96 large English towns the corresponding rate did not exceed 0·9, while in the 16 Scotch towns it reached 2·0 per 1000. The deaths attributed to scarlet fever, which had been 12, 5, and 13 in the three preceding weeks, declined to 8 in the week under notice, and were all registered in Belfast. The 8 deaths referred to diphtheria were 5 in excess of the average in the earlier weeks of the quarter, and included 4 in Dublin and 2 in Belfast. The 6 fatal cases of enteric fever, comprising 3 in Dublin and 3 in Newry, were 4 in excess of the average in the earlier weeks. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 18, 12, and 13 in the three preceding weeks, fell to 6 in the week mentioned, of which 4 occurred in Dublin. The 6 deaths referred to whooping-cough were slightly in excess of the average in the earlier weeks, and comprised 3 in Belfast, 2 in Galway, and 1 in Newtownards. The 2 fatal cases of measles occurred in Dublin. In addition to the above diseases a fatal case of typhus was recorded in Dublin.

The deaths referred to diseases of the respiratory system, which had been 68, 76, and 73, in the three preceding weeks, rose to 92 in the week under notice. Of the 407 deaths from all causes, 129, or 32 per cent., occurred in public institutions, and 5 resulted from various forms of violence. The causes of 19, or 4·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: R. A. Ross to the *Diana*, and for duty with group of ships of Third Fleet; E. A. Penfold to the *Egmont*; A. H. H. Vizard to the *Albemarle*; and R. H. Mornement to the *Zealandia*. Staff-Surgeons: W. E. Ormsby to the *Thunderer*; H. Cooper to the *Virid*; C. E. C. Stanford to the *President*, additional, for Recruiting Headquarters and other special duties; N. H. Harris to the *Weymouth*, on completing; and J. J. H. Rooney to the *Europa*. Surgeons: J. A. O'Flynn to the *Hebe*; and F. J. Burke to the *Pembroke*, additional, for disposal, to the *Sirius*, on commissioning, and to the *Alert*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Supernumerary Major David Harvey is restored to the establishment (dated Dec. 1st, 1913).

INDIAN MEDICAL SERVICE.

The King has approved of the promotion of the following Officers:—Lieutenant-Colonel to be Colonel: John Crimmin, V.C., C.B., C.I.E. (dated Oct. 1st, 1913). Major to be Lieutenant-Colonel: Ewan Cameron MacLeod (dated July 29th, 1913). Captain to be Major: Hugh Barkley Steen (dated July 29th, 1913).

The King has approved of the retirement of Major Edward Surman Peck (dated Dec. 6th, 1913).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Alexander C. Court to be Captain (dated Dec. 17th, 1913).

Cadet Sergeant Joseph Harold Baird, from the Edinburgh University Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Nov. 28th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

4th Southern General Hospital, Royal Army Medical Corps: Henry George Pinker to be Captain, whose services will be available on mobilisation (dated Oct. 21st, 1913).

3rd East Anglian Field Ambulance, Royal Army Medical Corps: Lieutenant William I. Cowell to be Captain (dated Nov. 10th, 1913).

Northumbrian Divisional Clearing Hospital, Royal Army Medical Corps: Lieutenant-Colonel (Honorary Lieutenant in the Army) John Clay, from the 1st Northumbrian Field Ambulance, Royal Army Medical Corps, to be Lieutenant-Colonel (dated Dec. 20th, 1913).

Attached to Units other than Medical Units.—Captain (Honorary Captain in the Army) George Black to be Major (dated Oct. 28th, 1913). Captain James A. Taylor resigns his commission (dated Dec. 20th, 1913).

For Attachment to Units other than Medical Units.—George Henderson to be appointed Lieutenant (dated Nov. 6th, 1913).

DEATHS IN THE SERVICES.

Brigade Surgeon Edward Footner, late A.M.S., died at Westcliff-on-Sea recently. He entered the service as an assistant surgeon in 1861, was promoted to surgeon in 1873, and to surgeon-major in 1876. He served in the Afghan war of 1878-80, and was present at the engagements at Ahmed Kheyl and Urzoo (medal and clasp). He retired in 1885.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the December issue of this journal Major J. C. B. Statham and Dr. G. G. Butler, of the West African Medical Staff, jointly contribute a note on Certain Bodies Found by Liver Puncture in a case of Fever associated with Splenic Enlargement. This note, which is published with the permission of the Yellow Fever Commission, describes some curious "bodies" having the appearance of masses of protoplasm stained as a rule a light blue or grey-blue colour and containing chromatin granules or "coccoid bodies." Major A. B. Smallman contributes a note on Some Cellular Bodies found in a case of Mediterranean Leishmaniasis. Both these notes are illustrated with coloured plates. The subject of the Utility of Enzymes in Malaria is discussed by Major F. W. Lambelle, the question of the Soldiers' Headdress is dealt with by Major R. J. Blackham, and a previous article on Staff Tours is continued by Major S. H. Fairrie.

NOTES FOR WOMEN'S VOLUNTARY AID DETACHMENTS.

A little book consisting of notes for the use of commandants of Women's Voluntary Aid Detachments in conducting meetings for first aid and nursing subjects when instruction by a medical officer or trained nurse is not available has just been issued.[1] The notes are divided into six sections, which cover the chief points in nursing and first-aid based on the manuals of the British Red Cross Society, each section being headed with a list of materials required and notes on practical work. These are followed by a series of questions with answers. The book should serve a useful purpose.

ARMY AND NAVY MALE NURSES' COÖPERATION.

The sixth annual report of this coöperation shows that progress has been made during the year and that the services of the male nurses are becoming more generally appreciated. Since June, 1912, 42 nurses have been regularly employed, and 319 patients have been nursed. The receipts have amounted to £3926 7*s.* 9*d.*, an increase of £206 11*s.* as compared with the previous 12 months. The institution is almost self-supporting, but outside support is still necessary if the excellent work which is being done is to be continued in a satisfactory manner. The address of the offices is 11A, Welbeck-street, Cavendish-square, London, W.

[1] Women's Voluntary Aid Detachments; Notes for Practice Meetings. London: Harrison and Sons. Pp. 88. Price 1*s.* net.

As the result of the performance given by the Strolling Players' Club at the Court Theatre on Nov. 19th in aid of the Royal Dental Hospital of London, the charity has benefited to the amount of £117.

LEEDS SCHOOL OF MEDICINE: ANNUAL DINNER OF PAST AND PRESENT STUDENTS.—The thirty-fifth annual dinner of the past and present students of the Leeds School of Medicine was held at the Queen's Hotel on Friday, Dec. 19th. Mr. G. Constable Hayes was in the chair, and there was a large attendance of the staff and of the students. A very cordial welcome was given to Mr. M. E. Sadler, the Vice-Chancellor, who has, since his first connexion with Leeds, shown such a keen interest in the medical side of the University. Students are remarkably quick to see anything of this kind, and the very enthusiastic manner in which the Vice-Chancellor was received was a fitting endorsement of the high esteem in which Mr. Sadler is held by the staff, who are gratified by the assiduity with which the academic head of the University attends the meetings of the board of the Faculty. In proposing the toast of the "Past and Present Students," Mr. Charles Lupton, chairman of the weekly board of the infirmary, referred to the intimate connexion which had always existed between the infirmary and the school. He commented on the causes which had resulted in Leeds being such a prominent centre of medical and of surgical knowledge while not itself what could be termed in the first rank of the provincial towns, and he attributed this to the long succession of distinguished men who had filled the position of honorary physicians and surgeons to the infirmary and to the good relationship which had always existed between the staff and the lay members of the board. The toast of "The Chairman" was proposed by Mr. H. R. Knowles and was heartily responded to by the meeting.

Correspondence.

"Audi alteram partem."

THE EBBW VALE WORKMEN'S MEDICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—I have to acknowledge your courtesy in publishing my letter of Dec. 15th in your last issue and also to express regret if I implied that the matter commented upon was in one of your leading articles; it was not, but it appeared in the report of your Special Commissioner.

In response to your suggestion I have obtained from one of the leading practitioners on the panel a statement of their terms of remunerations which are as follows: (1) The capitation fees as granted by the Monmouthshire Insurance Committee; (2) the sum of 13*s.* per annum for the dependents of married men only; (3) the sum of 4*s.* per annum for boys working between the ages of 14 and 16; and (4) half a guinea for midwifery (paid by the patient).

That is to say, for every married contributor the doctor receives £1 per annum, while for single contributors he takes the full capitation fee, and for boys under 16 the sum of 4*s.* per annum. Widows and orphans of previous contributors are entitled free to all the benefits of the institution. All drugs and dressings are supplied by the society.

Your Special Commissioner states that during the last "great strike"—I am not quite certain as to which strike this alludes—the doctors in Monmouthshire and South Wales did not receive a penny. Again, I cannot answer for other districts, but of my own knowledge during the coal strike of some six weeks' duration in the spring of 1912 all salaries were paid punctually and fully by the Ebbw Vale Workmen's Doctors Fund. And again, during some five or six months in the autumn and winter of the preceding year, when the works were "shut down"—the works as distinct from the collieries—and the income of the fund being in consequence greatly diminished—not a doctor or an official had to wait for or went short of a penny! Moreover, in the strike in 1898, which lasted some six months, 75 per cent. of all salaries were paid by the fund.

It is worth noting, too, that under the present constitution of the committee of the Ebbw Vale Workmen's Medical Society the "panel" practitioners have direct representation on that committee when any financial matters are under discussion at its usual monthly meetings.

It is a matter for comment that while other societies are violating these "fundamental" principles without any notice of such violation being taken by the British Medical Association, the Ebbw Vale Medical Society—whichever may have been in the right in the controversy between the old Ebbw Vale Workmen's Doctors' Fund and the Association—should still remain under the public ban, nominal or otherwise, of an Association which professes to champion the cause of fairplay in professional relationships and in the relationship between the profession and the general public.

I am, Sir, yours faithfully,

HUGH N. TAYLOR, M.A., M.D., F.R.C.S.

Ebbw Vale, Dec. 19th, 1913.

THE GOVERNMENT OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—The letters which you have recently published from Mr. R. Brudenell Carter and Dr. Sidney C. Lawrence and your leading articles on the constitutional changes in the British Medical Association and on advertising and canvassing under the National Insurance Act are sufficient evidence to prove that all is not well with the government of the medical profession.

On the one side there are men who consider that the management of affairs by those in authority is hopelessly bad, and who demand representation on the governing councils, and on the other side men who possess representation or who serve upon the governing councils. The former have a strong case, but formulate their position faultily and prejudice it, and the latter are frankly hopeless. Mr. Carter represents the position adopted by the latter, who after prolonged gestation have passed an examination which admits them to the privileges of representation and governing powers. They rely upon examinational tests as evidence of their special aptitude for administrative and governing powers. Now examinations are useful only to those who have derived benefit from the course of study which the examinations compel. They are useless to those who pass them and who have simply crammed up examinational knowledge sufficient for a pass. It is to be feared that the latter class outnumbers the former. If the actions of some who represent our professional government are taken as the test of efficiency, surely examinational attainments are things to be avoided.

It appears to many of us that those in power assume the position of the intellectual in politics and desire to exercise the function of a benevolent autocracy. I am not one of those who are unable to recognise the fact that a benevolent autocracy is probably one of the best forms of government, but in these days it is not satisfactory, especially when exercised by a body of men, some of them possessing a high degree of examinational knowledge, a few some scientific distinction, and an infinitesimal number practical training in administration. Scientists at their best are very seldom men who have the qualities of leaders of men or of thought.

We are in need of some fresh blood in our council chambers.

When the British Medical Association was reconstructed some years ago I advocated strenuously that reconstruction because I hoped that a body would be formed which would be capable of administering the affairs of the medical profession. Having seen the completion of the machinery, I advocated the appointment of a secretary who possessed administrative experience, and preferably some legal experience in addition. It was decided, however, to appoint a man who had no such experience and to retain the subscription, which in my opinion was inadequate for the work which was to be performed.

With the appearance of the National Insurance Act we have witnessed a complete fiasco. The democratic constitution provided for the British Medical Association has failed to produce administrators of sufficient capacity, and the reputation of the medical profession has sunk. Two types of government have failed, and it has therefore

occurred to me that a blend might produce more encouraging results. A council nominated by the Royal Colleges, the British Medical Association, and by the two Defence Societies in proper proportions ought to provide the autocratic, the democratic, and the intellectual elements which are necessary. The Royal Colleges are statutory bodies which were always consulted by Government departments when they required information relative to public business connected with medical affairs. These Colleges have failed conspicuously in filling the place which was assigned to them, and it appears reasonable that the work for which they are unfitted should be taken from them and assigned to such a council as I propose, and more especially in view of the fact that neither has made any attempt to introduce any democratic element into their governing councils.

I am, Sir, yours faithfully,

Hatfield, Dec. 16th, 1913. LOVELL DRAGE.

Home and Foreign Notes.

(FROM OUR OWN CORRESPONDENTS.)

SCOTLAND.

Edinburgh University Graduation Ceremony.

THERE was the largest winter graduation which has ever taken place at the ceremony in the M'Ewan Hall on Dec. 17th, when Principal Sir William Turner conferred the degrees, 18 candidates receiving the degree of Doctor of Medicine, 1 the degree of Doctor of Science, 77 the degree of Bachelor of Medicine and Bachelor of Surgery, and 3 the degree of Bachelor of Science. Principal Turner, in his address, described the list as a highly representative one, both as regarded the inclusion of the two sexes and as regarding the source from which the graduates came, for there was a strong representation from India, Africa, Australasia, and the West Indies, while the continent of Europe had also made contributions to their work. Prior to the ceremony a programme of music was performed on the grand organ by Mr. Collinson, organist to the University.

Hostels for Edinburgh Women Students.

An interview has taken place between representatives of the Scottish Education Department and Provincial Committee and the Edinburgh Association for the Provision of Hostels for Women Students, a report of which will be submitted to the Edinburgh Provincial Committee for the Training of Teachers. It states that Sir John Struthers, the secretary of the Scottish Education Department, has asked for a conference mainly in connexion with the financing of the scheme. Whereas the Provincial Commiteee's contribution to capital expenditure would be made in full directly from their funds, the contribution made on behalf of the University would be in the form of a loan from the Carnegie trustees, bearing interest, so that under the scheme proposed the interest would be borne by the whole body of students in residence, an arrangement which would have the effect of placing upon the students under the Provincial Committee responsibility for a proportion of the interest chargeable on the contribution to capital made solely for University students. It was explained to Sir John Struthers that the advantages accruing to the Provincial Committee and their students from the combination would more than compensate for any slight increase in fees due to the interest in question, when he gave his cordial approval to the joint scheme. On account of the capital sums involved five-sevenths of the total accommodation will be allocated to the Provincial Committee and two-sevenths to the University.

Appointment of Medical Specialists.

At a meeting of the Dundee School Board held lately the following were appointed in connexion with the treatment of the children:—Dentists: H. Gordon Campbell, Dundee, and E. E. Cassaday, Broughty Ferry; eye specialist: J. Strathearn, M.D., Dundee; ear, nose, and throat: Robert P. Mathers, M.D., Dundee; and skin: George A. Pirie, M.D., Dundee.

Dec. 22nd.

IRELAND.

The Certification Question.

MEDICAL opinion in Ireland is divided at present as to the best system of certification of insured persons, assuming that the terms agreeable to the profession can be arranged between the Commissioners and the Irish Medical Committee. Many medical men, and particularly those engaged in the Poor-law service, think that a panel for certification such as is at present working in several areas will furnish the most satisfactory arrangement. On the other hand, the working of the panel has caused dissatisfaction to many of the Approved Societies, and much evidence in condemnation of it was offered to the recent committee of inquiry appointed by the Insurance Commissioners. The only alternative to the panel is a pooling system by which arrangements for certification would be made somewhat on the model of the arrangements for medical benefit at present in force in Manchester. Under a pooling scheme the entire sum available for certification in a given area would be divided among all practitioners who certified in proportion to the number of certificates signed by each. This scheme, if fairly worked, would be equitable while settling the problem of paying for the certificates of hospital patients. The pooling scheme requires safeguards to prevent too free issuing of certificates, but if the Local Medical Committees were the administrators the check of professional opinion would have considerable effect, as it would be to the interest of the local profession as a whole to prevent the giving of loose certificates. As between a panel and a pooling scheme, it might be arranged that the profession in each area should exercise a reasonably terminable option. It is to be hoped that some arrangement may be made within the next few weeks so that the entire grant promised for next year by Mr. Lloyd George may be made available.

British Dental Association: Irish Branch.

The annual general meeting of the British Dental Association was held last week in the Royal College of Surgeons, the President, Mr. Kevin E. O'Duffy, in the chair. The roll of membership showed an increase during the year. Mr. T. J. Rea, of Belfast, was elected president for the ensuing year. In the evening the annual dinner was held in the Shelbourne Hotel, the Lord Lieutenant being present.

Dec. 22nd.

VIENNA.

Reforms in the Army Medical Corps.

THE report of the Ministry of War to the Austrian House of Parliament contains a few figures which show that our military authorities are at last beginning to recognise the importance of improving the conditions of service in the army medical department. We have at present 410 fully trained surgeons who have served at least one year in surgical clinics within the last ten years, and have moreover served various terms in special clinics for diseases of the ear, eye, nose, throat, and skin. Promotion has also been accelerated so that a medical officer of the army may be sure of attaining the rank of staff surgeon after from 12 to 15 years of service. Scholarships in the different university clinics have been again increased both in number and extent. The staff of male nurses has been increased, so that the relation between the number of patients and of attendants in the military hospitals is at present satisfactory. It is intended that in future 3 per cent. of the total expenditure on the army shall be devoted to the medical department, whereas at present only a little over 2 per cent. is used in this way. The miscellaneous requisites for the medical service of the army, such as X ray apparatus, appliances for sterilisation and for the filtration of water, hospital cars, &c., will be completely modernised.

Grievances of Medical Students.

As already mentioned in one of my letters the medical students of Vienna had struck work because of various alleged grievances arising out of the system of examinations. Negotiations between their representatives and the university authorities have resulted in an understanding on the following lines being arrived at. The students who are chiefly affected—namely, those who began their studies under the old regulations—will be examined up to the end of the year 1914 under the old conditions. Some other grounds of complaint, however, pertaining to the change in the mode of serving in the army could not be modified, as they are not under the control of the teaching authorities. Formerly medical students, who were physically fit for the duties, had to serve with the colours for six months, and after having taken the degree of M.D. they had to spend a second period of six months in attending military hospitals, but now they have to serve for three months (July, August, September) with the colours and then to spend nine months in hospitals, at first in a position not much above that of a mere male nurse, but eventually as a military surgeon. The negotiations have in the main served their purpose, for the students have resolved to take up their studies again.

Occupational Skin Diseases.

At a recent meeting of the Vienna Medical Society Dr. Oppenheim, acting on a suggestion mentioned in my last letter, read a paper on the Diseases Produced in Several Occupations by Handling Irritating or Otherwise Injurious Substances. The results are for the most part tylotic changes of the skin, or burns and scalds; diseases of the sudoriparous and sebaceous glands; diseases of the nails, toxic erythema, eczema, and infections of the skin. The skin is frequently coloured in a characteristic way, as in the case of anilin dye workers, printers, and shoemakers, or injured by small particles of iron or stone. Acids and caustics produce burns; molten metal causes burns of the legs chiefly, and the ulcers which are left require a long time for healing. Diseases of the sweat glands or sebaceous glands are caused by inhalation (iodine) or by the external action of irritative substances, such as pitch, paraffin, resin, or machine grease. Watchmakers, laundry-women, and photographers frequently show diseases of the nails, whilst some persons, who have special idiosyncrasies in regard to different substances, suffer from toxic dermatitis. This holds good chiefly with workers who handle several kinds of wood containing alkaloids, such as satinwood and sandal wood. Eczema often attacks persons engaged in the manufacture of jute, turpentine, lime, flour, and margarine or other artificial fats. Erysipelatoid diseases are frequent in butchers, and trichophytia in stablemen or men who ride and drive horses. Tuberculous disease of the skin and verruca tuberculosa (lupus), as well as vaccinia and syphilitic infections, have been transmitted by apparatus infected by previous users. All these diseases cost the factories and the Krankenkassen a good deal of money in the form of sick pay and grants during unemployment. It is therefore important to obtain coöperation between medical men, employers of labour, and sanitarians. These precautionary measures alone are not sufficient; there are many cases in which harmless substitutes for the injurious materials are the only possible means of relief, and these have in the first place to be discovered.

Dec. 20th.

CONSTANTINOPLE.

A Special Sanitary Commission.

A SPECIAL Sanitary Commission has left Constantinople for the cities of Bassora, Bagdad, Kerbela, and Hannekine for the purpose of studying the question of erecting sanitary and hygienic stations for the pilgrims. It consists of Dr. Fritz Schoenberg (the second dragoman of the German Embassy), Dr. Frank G. Clemow (the British delegate on the Ottoman Board of Health), Dr. Walter (the physician of the Russian Embassy), and Dr. Djenab Shehabeddine Bey (representing the Ottoman Government). The realisation of the scheme, if properly executed, will prove of great benefit not only to the pilgrim world of Shiah and Sunnah alike, but to the whole of the Near East. As is well known, the above cities form some of the most important centres of Moslem pilgrimage to the holy places of Islam, Mecca and Medina. Kerbela, besides, is visited every year by many thousands of Shiah Islamites in order to worship the tombs of the Persian saints Hussein and Hassan. Yet the sanitary conditions in those places are deplorable. The Commission proposes to investigate the matter thoroughly. Success may be expected to crown the effort, for the Commissioners are noted for their insight, energy, and knowledge of Eastern conditions.

Tuberculosis in Constantinople.

Dr. Witting Pasha, the German specialist on tuberculosis, in charge of the Gulhaneh Hospital, Stambul, has exhibited, in a special building, charts showing various statistics dealing with the subject of tuberculosis. From these it appears that in an annual mortality of about 17,000 there are 2756 victims of tuberculosis, a percentage of 16·2. A table of deaths according to nationality is given. The available statistics show that Moslems constitute about 52 per cent. of the population of the

city, Greeks about 30 per cent., Armenians about 12 per cent., and Jews nearly 6 per cent. Of deaths from tuberculosis 62 per cent. are among Moslems, 24 per cent. among Greeks, 9 per cent. among Armenians, and 4·5 per cent. among Jews. The following table shows the number of deaths among men and women of different nationalities:—

Moslems	756 men	943	women.
Greeks	440 ,, ...	219	,,
Armenians	156 ,, ...	96	,,
Jews	68 ,, ...	54	,,

The causes for the great mortality among the Moslem women are chiefly the harem seclusion and the wearing of the veil. Dr. Witting's investigations demonstrate that the ravages among the higher and middle classes of Islamite women are much greater than among the lower classes, and it is exactly among the latter that there is far more freedom regarding the wearing of the veil and the enjoyment of outdoor life.

The late Dr. Zambaco Pasha.

Dr. Zambaco Pasha, the private physician of the Khedival family, died in Cairo last week. He was a well-known specialist of skin diseases, and distinguished himself by his investigations into leprosy, upon which subject he published a number of books. With him disappears a great figure in the medical world of the Orient. His scientific attainments were of a high order. He was born in the Turkish capital in 1831, and studied in Paris, where he obtained his medical qualifications. He took part as a surgeon in the Franco-German war, after which he established himself in Constantinople. He was a member of the Medical Academies of Paris, St. Petersburg, and Vienna. He had received numerous decorations. The French Club in Constantinople named its principal hall after him, and here is now preserved his extensive library.

Cholera.

Cholera seems to be spreading here. Official accounts, which are never accurate, announce only 3–5 deaths daily, but there must be more, especially on the Asiatic side. Fortunately very cool weather has now set in, and it is hoped that the city will escape this time from a serious epidemic. The medical authorities are taking all preventive measures.

Dec. 13th.

THE AFTER-CARE ASSOCIATION.—The After-care Association for Poor Persons Discharged Recovered from Asylums for the Insane appeals for funds to carry on and extend its work. This association, which is the only one of its kind in the United Kingdom, assists cases in all parts of the country, and last year 391 cases were considered by the council. Subscriptions and donations will be thankfully received by the secretary, H. Thornhill Roxby, Church House, Westminster, S.W. Bankers—Union of London and Smiths, Victoria-street, Westminster.

DONATIONS AND BEQUESTS.—By will the late Mr. William B. Gurteen has left £500 each to Addenbrooke's Hospital, Cambridge, and the Colchester Asylum for Idiots. The late Mr. Thomas P. Borrett has left £1000 to Charing Cross Hospital for the endowment of a bed.—The treasurers of the Middlesex Hospital Cancer Charity have received from the executors of the late Mr. Rutherford £500 for the purposes of cancer research.—A friend of the Maharajah of Nepal has given £1300 towards the endowment of the research laboratories at the Hospital for Consumption, Brompton.—Mr. Samuel Taylor, of Manchester, has given a donation of £1000 to the central branch building fund of the Manchester Royal Infirmary in commemoration of his eighty-sixth birthday.

THE NATIONAL INSURANCE ACT.

ISSUE OF PROVISIONAL REGULATIONS.

PROVISIONAL Regulations dated Dec. 2nd have been issued by the Insurance Commissioners to govern the election to Insurance Committees of the two members who are to be elected (under Section 59 (2) (*c*) of the Act of 1911) by all the medical practitioners of a county or borough if no association has been formed for the purpose. These regulations are to be cited as the National Health Insurance (Insurance Committees: Election of Medical Representatives) Regulations (England) (No. 2), 1913. On the same date have been issued Provisional Regulations governing the application of the first mentioned or principal regulations so far as the Dewsbury, Barnsley, and Wallasey committees are concerned. The price of each document is 1*d*.

NATIONAL MEDICAL GUILD.

A meeting of medical practitioners was held on Dec. 19th at the Hammersmith Town Hall under the auspices of the National Medical Guild. The chair was taken by Dr. Charles Buttar, president of the guild, who, after a few introductory words, called upon Mr. E. B. Turner to open the discussion on the Value of Trade Unionism to the Medical Profession. Mr. Turner then argued in favour of the formation of a strong medical trade union apart from, but not opposed to, the British Medical Association, which by its constitution cannot become such a body. Mr. F. M. Boclet maintained that the present difficulty was due to the apathy of individual medical men. Mr. H. H. Tomkins agreed that the units in the medical profession had themselves to blame for the present situation, because they had failed to take proper interest or give adequate support. He still, however, thought that the British Medical Association was the body to which all should turn. Mr. P. C. Raiment, general secretary, then described the origin and progress of the guild, and instanced the case of Zetland *v.* British Medical Association as an example of the disabilities under which a body, when unregistered as a trade union, labours. He maintained that a "warning notice" could always be interpreted legally as "an act in restraint of trade." He announced that steps were being taken to link up the guild with the medical practitioners' trade union at Leicester. Mr. M. Milton Townsend proposed a resolution pledging those present to support the National Medical Guild and compel recognition of it by the British Medical Association. This was put to the meeting by the chairman and carried, and the proceedings ended with a warm vote of thanks to Dr. Buttar.

LONDON INSURANCE COMMITTEE.

It was reported to the London Insurance Committee on Dec. 18th that the number of practitioners on the panel in November last was 1458, of whom 88 were medical officers of institutions. The total in October was 1437 and in July 1396. The latest total of insured persons was 1,548,203. The committee approved the principle of the examination at local centres of applicants for sanatorium benefit in institutions. Up to the present only two centres have been available, and this has been found inconvenient to all concerned. Nine complaints by insured persons against practitioners were dealt

with recently. Four complaints of neglect were found to be unsubstantiated; in two cases there was a conflict of evidence and no action was taken. The Medical Service Subcommittee found to be proved an allegation against a practitioner that he adopted an offensively familiar attitude towards a woman patient, and that he gave advice of an improper and unprofessional character. Mr. Warburg, the chairman of the subcommittee, said the question was being considered whether censures could be made more effective in cases of professional misconduct by making communications to the Local Medical Committee or possibly the General Medical Council. The committee declined to reopen the question of the distribution of the unallotted funds in order that a resolution to rescind the previous decision to take further legal advice might be moved.

CLAUSE 2 (ii.): ACTION IN EAST SUFFOLK.

On Dec. 16th, at a meeting of the East Suffolk Insurance Committee, Dr. T. Cuming Askin remonstrated against the haste in which the new agreement had been placed before the profession, and proposed that the Committee should agree to the following words being inserted in the agreement, which words had been accepted by the Commissioners in connexion with another committee:—

That nothing in the agreement shall be considered as prohibiting the acceptance by a practitioner of such fees as may have been agreed to between them in writing as a condition of the acceptance by the practitioner of the insured person where the places of residence of the practitioner and the patient are so situated that the access is difficult or inconvenient, and where there is another practitioner on the panel living nearer to whom the patient might be assigned.

The proposal was not accepted, and in the end a long resolution prepared by the clerk to the Committee was adopted, which ran as follows:—

That in order to remove doubts which have arisen as to the construction which may be placed upon Clause 2 (ii.) of form Med. 29 (revised), this committee would, where circumstances justified, and subject to the approval of the Medical and Sanatorium Benefits Subcommittee being obtained on each separate case submitted to them, consider the clause to mean that nothing in Clause 2 (ii.) of the agreement shall be read as prohibiting the acceptance by the practitioner from an insured person of such fees as may have been agreed between them in writing as a condition of the acceptance by the practitioner of the insured person where the places of residence of the insured person and the practitioner are so situated that access between them is by reason of distance or otherwise difficult or inconvenient, and where there is another practitioner upon the panel by whom the insured person might have been accepted, or to whom he might have been assigned, and whose residence is nearer to that of the insured person, or is less inconvenient of access, subject, however, to the proviso that it must be clearly understood that the passing of this resolution will not in any way admit the right of the practitioner to claim fees in these or in other circumstances, but will merely enable him to enter into an agreement with the insured person who desires and offers to do so in the circumstances indicated.

Dr. Askin then asked the Committee to agree to a minute:—

That the phrase "accept any fee or other remuneration" does not include a present or a gift made by an insured person to a doctor.

This minute, the principle of which had been agreed to by the Middlesex Committee, was eventually adopted. Although, therefore, the desired amendment cannot be inserted in the new agreement, every practitioner on the panel will understand his position from the minute.

COMPLIMENTARY DINNER TO DR. C. ADDISON, M.P.

The Chancellor of the Exchequer will preside at a complimentary dinner to Dr. Addison, to be held on Feb. 3rd, 1914. Application for tickets should be made to Sir John Collie, M.D., 25, Porchester-terrace, London, W., or to Dr. H. H. Mills, 21, St. Mary Abbot's-terrace, Kensington, London, W.

Medical News.

EXAMINATION RESULTS.—The results of the December examinations at the Universities of London, Manchester, Liverpool, and Leeds, and at the Society of Apothecaries of London will be given next week. The demands on our space prevent their appearance this week.

HARVEIAN SOCIETY.—The annual general meeting of the Harveian Society of London will be held on Thursday, Jan. 8th, 1914, at the Stafford Rooms, Tichborne-street, Edgware-road, W., when the officers for the ensuing year will be elected, and reports will be received from the treasurer and honorary secretaries. Dr. Leonard Guthrie will deliver his presidential address on the Early Transactions of the Harveian Society. The new president will be invested and the proceedings will terminate with a smoking concert.

THE BEIT FOUNDATION FOR MEDICAL RESEARCH.—At a meeting of the trustees of the Beit Memorial Fellowships for Medical Research, which was held on Dec. 17th, the following were elected to Fellowships. Each Fellowship is of the annual value of £250, and the usual tenure is for three years, with in exceptional cases a possible extension for one year:—J. O. W. Barratt, M.D. Lond. (proposed research: Study of substances contained in or derived from blood plasma, to be carried out in Lister Institute of Preventive Medicine). Myer Coplans, M.D. Lond., State Medicine (proposed research: Study of immunity with reference to action of silicates, to be carried out in the Lister Institute). E. C. Grey, B.Sc. Sydney (proposed research: Bacteriological Chemistry, to be carried out in the Lister Institute). J. R. Marrack, M.B. Cantab. (proposed research: Chemical pathology of arthritic diseases, to be carried out at the Cambridge Research Hospital). V. H. K. Moorhouse, B.A. Univ. Toronto, George Brown Memorial Scholar (proposed research: Metabolism of animals with special reference to diabetes, to be carried out in the Institute of Physiology of the University of London). G. E. Nicholls, A.R.C.S., D.Sc. Lond. (proposed research: Investigation of the structure of the sub-commissural organ and Reissner's fibres and the study of the pineal region of the brain, to be carried out at King's College, London). Annie Porter, D.Sc. Lond. (proposed research: Parasitic entozoa, to be carried out in the Quick Laboratory, Cambridge; the Liverpool School of Tropical Medicine; and, if possible, the King Institute of Preventive Medicine, Madras, or the Wellcome Research Laboratories, Khartoum). J. G. Priestley, M.B. Oxon. (proposed research: Factors concerned in the regulation of the excretion of urine, to be carried out at the Physiological Department of the University of Oxford). Jane J. Robertson, M.B. Glasg. (proposed research: Comparative anatomy and physiology of the heart and the study of the vertebrate nervous system, to be carried out in the Victoria Infirmary, Glasgow). Marjory Stephenson, Cambridge Natural Science Tripos, Part I. (Chemistry, Physiology, and Zoology) (proposed research: Metabolism of fats and its relation to carbohydrates, to be carried out in the Institute of Physiology, University College, London). J. G. Thomson, M.B. Edin. (proposed research: Toxins and antibodies in protozoa, to be carried out in the Lister Institute). At the same meeting Dr. F. Gowland Hopkins, F.R.S., reader in chemical physiology in the University of Cambridge, and praelector in biochemistry at Trinity College,

was appointed a member of the advisory board in the place of Sir William Osler, Bt., F.R.S., resigned, and the Francis Galton Eugenics Laboratory was recognised as a place of research. It was also announced that Mr. Thomas Renton Elliott, M.D. Camb., one of the Fellows, had been elected a Fellow of the Royal Society.

METROPOLITAN HOSPITAL SUNDAY FUND.—In the unavoidable absence of the Lord Mayor, Sir John Bell presided at the annual meeting of the constituents of this Fund, which was held at the Mansion House on Dec. 19th. The report stated that the year's collection, the forty-first, had resulted in a total of £64,991 15*s.* 1*d.*, a decrease of £2981 compared with last year. The collections in the various places of worship had resulted in a sum of £28,434, being £7432 less than in 1912. A portion of this decrease is accounted for by the discontinuance of the practice of adding donations to the amount of about £4000 to the collection at St. Paul's Cathedral. The net falling off in the church collections is about £3000. In a note to the report the council view with apprehension the continued falling off in the church collections, which not only presses hardly on the hospitals, but also upon the clergy and ministers of the poorer congregations by reducing the power of the Fund to give surgical appliance grants and hospital and convalescent home letters. On the motion of the Rev. Canon Pearce, seconded by Sir Savile Crossley, who pointed out that notwithstanding the falling off in the collections of various places of worship a larger sum of money had been distributed than in previous years, owing largely to the judicious management of the finance committee, the report was adopted. Vacancies on the council having been filled by election or re-election, Hospital Sunday for 1914 was fixed for June 14th, and a vote of thanks to the chairman terminated the proceedings.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

VITAL STATISTICS OF THE GOLD COAST.

IN his report on the Blue-book of the Gold Coast Colony and its dependencies for the year 1912, Mr. W. C. F. Robertson, Acting Colonial Secretary, gives the population as 1,503,386, the number of Europeans being 2367. Amongst the latter there were 28 deaths. These included 8 officials; in 2 cases death was due to yellow fever, in 2 to blackwater fever, and in 2 to malaria, the remaining 2 being due to non-climatic causes. Thirteen European officials were invalided during the year owing to: malaria, 3; blackwater fever, 2; neurasthenia, 2; adenitis, 1; neuritis, 1; various, 4. Sixty-two non-official Europeans were invalided owing to: malaria, 22; blackwater fever, 6; dysentery, 6; anæmia, 3; gastritis, 2; various, 23. The total number of Europeans coming under treatment was 1004, as against 878 in 1911. No means exist whereby accurate statistics relating to the health of natives can be obtained, but the returns show that the number of attendances for hospital and dispensary treatment was 25,964, or 1767 more than in the previous year. Treatment was given for 2282 cases of malaria, 1931 of helminthic diseases, and 549 for dysentery. There were several outbreaks of small-pox in the eastern province of the colony, and slight outbreaks also occurred in the central and western provinces. The number of successful vaccinations performed was 23,232. There were 104 cases of sleeping sickness reported during the year with 3 deaths. There were 3 cases of yellow fever among natives in Accra, all of whom recovered. The new European hospital at Accra has not yet been completed, but the existing hospital, which comprises 3 European and 4 native wards, containing 7 and 25 beds respectively, was made mosquito proof. The hospital at Seccondee consists of 6 European wards, including 2 for convalescents, with a total of 16 beds, while for native patients 4 wards with 20 beds are provided. At Cape Coast there is accommodation for 13 Europeans, and 4 wards containing 19 beds for native patients. At Coomassie there is a European hospital with 4 wards, and a native hospital with 3 wards. European nursing sisters are attached to the Accra, Seccondee, and Coomassie hospitals. There are a lunatic asylum and a laboratory at Accra and a special sleeping sickness hospital at Anum. The sanitary conditions under the sanitary branch of the medical department show generally a marked improvement, but the inadequacy of water-supplies remains a cardinal difficulty. There is a pipe-borne supply at Obuasi in Ashanti, and waterworks at Accra and Seccondee are in course of construction. The climate, though hot and damp, is cooler than that of most tropical countries situated in similar latitudes. It is not in itself unhealthy, but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases, against which all possible precautions have constantly to be taken. The rainy season is marked by a considerable fall in the temperature, which is found to be refreshing to many Europeans, but proves trying to some.

H. B. asks where he could obtain a cheap reproduction of the picture, "The Doctor," by Sir Luke Fildes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced. In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.

September (Vienna).—Third International Congress for Diseases of Occupation.

(London).—Anglo-American Exhibition.

(Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.

(Auckland, N.Z.).—Australasian Medical Congress.

(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page for the current half year are published in this issue, which completes the second volume of the year 1913.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1913 will be ready shortly. Bound in cloth, gilt lettered, price 16*s*., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

METEOROLOGICAL READINGS.
